1. Introduction

The purpose of this article is to establish algebraicity criteria for formal germs of curves in algebraic varieties over number fields and to apply them to derive a rationality criterion for formal germs of functions, which extends the classical rationality theorems of Borel-Dwork ([6], [21]) and Pólya-Bertrandias ([39], [1], Chapter 5; see also [16]) valid over the projective line to arbitrary algebraic curves over a number field.

Our algebraicity criteria improve on the ones in [12] and [13], which themselves were inspired by the papers [18] and [19] of D. V. and G. V. Chudnovsky and by the subsequent works by André [2] and Graftieaux [26, 27]. As in [12] and [13], our results will be proved by means a geometric version of “transcendence techniques”, which avoids the traditional constructions of “auxiliary polynomials” and the explicit use of Siegel’s Lemma, replacing them by a few basic concepts of Arakelov geometry. In the proofs, our main objects of interest will be some evaluation maps, defined on the spaces of global sections of powers of an ample line bundle on a projective variety by restricting these sections to formal subschemes or to subschemes of finite lengths. Arakelov geometry enters through the estimates satisfied by the heights of the evaluation maps, and the slopes and Arakelov degrees of the hermitian vector bundles defined by spaces of sections (see [17] and [14] for more details and references on this approach).

Our main motivation in investigating the algebraicity and rationality criteria presented in this article has been the desire to obtain theorems respecting the classical principle of number theory that “all places of number fields should appear on an equal footing” — which actually is not the case in “classical” Arakelov geometry and in its applications in [12]. A closely related aim has been to establish arithmetic theorems whose geometric counterparts (obtained through the analogy between number fields and function fields) have simple formulations and proofs. These concerns led us to two technical developments in this paper: the use of (rigid) analytic geometry over p-adic fields to define and estimate local invariants of formal curves over number fields([1]), and the derivation of a rationality criterion from an algebraicity criterion by means of the Hodge index theorem on (algebraic or arithmetic) surfaces.

Let us describe the content of this article in more details.

In Section 2, we discuss geometric analogues of our arithmetic theorems. Actually, these are classical results in algebraic geometry, going back to Hartshorne [32] and Hironaka-Matsumura [34]. For instance, our algebraicity result admits as analogue the following fact. Let $X$ be a quasi-projective variety over a field $k$, and let $Y$ be a smooth projective integral curve in $X$; let $\hat{S}$ be a smooth formal germ of surface through $Y$ (that is, a smooth formal subscheme of dimension 2, containing $Y$, of the completion $\hat{X}_Y$). If the degree $\deg_y N_Y S$ of the normal bundle to $Y$ in $\hat{S}$ is positive, then $\hat{S}$ is algebraic.

\[\text{[1]}\] Since the first version of this paper was written, the relevance of rigid analytic geometry à la Berkovich to develop a non-archimedean potential theory on p-adic curves, and a “modern” version of Arakelov geometry of arithmetic surfaces satisfying the above principle of “equality of places” has been largely demonstrated by A. Thuillier in his thesis [47].
Our point is that, transposed to a geometric setting, the arguments leading to our algebraicity and rationality criteria in the arithmetic setting — which rely on the consideration of suitable evaluation maps, and on the Hodge index theorem — provide simple proofs of these non-trivial algebro-geometric results, in which the geometric punch-line of the arguments appears more clearly.

In Section 3, we introduce the notion of \( A \)-analytic curve in an algebraic variety \( X \) over a number field \( K \). By definition, this will be a smooth formal curve \( \hat{C} \) through a rational point \( P \) in \( X(k) \) — that is, a smooth formal subscheme of dimension 1 in the completion \( \hat{X} \) — which, firstly, is analytic at every place of \( K \), finite or infinite. Namely, if \( v \) denotes any such place and \( K_v \) the corresponding completion of \( K \), the formal curve \( \hat{C}_{K_v} \) in \( X \) deduced from \( \hat{C} \) by the extension of scalars \( K_v \to K \) is the formal curve defined by a \( K_v \)-analytic curve in \( X(K_v) \). Moreover the \( v \)-adic radius \( r_v \) of the open ball in \( X(K_v) \) in which \( \hat{C}_{K_v} \) “analytically extends” is required to “stay close to 1 when \( v \) varies”, in the sense that the series \( \sum_v \log r_v^{-1} \) has to be convergent. The precise formulation of this condition relies on the notion of size of a smooth analytic germ in an algebraic variety over a \( p \)-adic field. This notion was introduced in [12], 3.1; we review it in Section 3.A, adding some complements.

With the above notation, if \( \mathcal{X} \) is a model of \( X \) over the ring of integers \( \mathcal{O}_K \) of \( K \), and if \( P \) extends to an integral point \( P \) in \( X \) over \( \mathcal{O}_K \), then a formal curve \( \hat{C} \) through \( P \) is \( A \)-analytic if it is analytic at each archimedean place of \( K \) and extends to a smooth formal surface \( \hat{S} \) in \( \hat{X} \). For a general formal curve \( \hat{C} \) that is analytic at archimedean places, being an \( A \)-analytic germ may be seen as a weakened form of the existence of such a smooth extension \( \hat{S} \) of \( \hat{C} \) along \( P \). In this way, an \( A \)-analytic curve through the point \( P \) appears as an arithmetic counterpart of the smooth formal surface \( \hat{S} \) along the curve \( Y \) in the geometric algebraicity criterion above.

The tools needed to formulate the arithmetic counterpart of the positivity condition \( \deg_Y N_Y \hat{S} > 0 \) are developed in Section 4. We show how, for any germ of analytic curve \( \hat{C} \) through a rational point \( P \) in some algebraic variety \( X \) over a local field \( K \), one is led to introduce the so-called canonical semi-norm \( \| \cdot \|_{X, \hat{C}}^{\text{can}} \) on the \( K \)-line \( T_P \hat{C} \) through the consideration of the metric properties of the evaluation maps involved in our geometric version of the method of auxiliary polynomials. This extends a definition introduced in [13] when \( K = \mathbb{C} \). In Section 5, we discuss the construction of Green functions and capacities on rigid analytic curves over \( p \)-adic fields. We then extend the comparison of “canonical semi-norms” and “capacitary metrics” in [13], 3.4, to the non-archimedean setting.

In Section 5, we apply these notions to formulate and establish our algebraicity results. If \( \hat{C} \) is an \( A \)-analytic curve through a rational point \( P \) in an algebraic variety \( X \) over some number field \( K \), then the \( K \)-line \( T_P \hat{C} \) may be equipped with a “\( K_v \)-adic semi-norm” for every place \( v \) by the above construction — namely, the semi-norm \( \| \cdot \|_{X_{K_v}, \hat{C}_{K_v}}^{\text{can}} \) on

\[
T_P \hat{C}_{K_v} \cong T_P \hat{C} \otimes_K K_v.
\]

The so-defined metrised \( K \)-line \( T_P \hat{C} \) has a well defined Arakelov degree in \( [−\infty, +\infty] \), and our main algebraicity criterion asserts that \( \hat{C} \) is algebraic if the Arakelov degree
\[ \text{deg} T\hat{P} \hat{C} \text{ is positive.} \] Actually, the converse implication also holds: when \( \hat{C} \) is algebraic, the canonical semi-norms \( \norm{\cdot}_{X_k, \hat{C}_k} \) all vanish, and \( \text{deg} T\hat{P} \hat{C} = +\infty \).

Finally, in Section 6, we derive an extension of the classical theorem of Borel-Dwork-Pólya-Bertrandias, giving a criterion for the rationality of a formal germ of function \( \varphi \) on some algebraic curve \( Y \) over a number field. By considering the graph of \( \varphi \) — a formal curve \( \hat{C} \) in the surface \( X := Y \times A^1 \) — we easily obtain the algebraicity of \( \varphi \) as a corollary of our previous algebraicity criterion. In this way, we are reduced to establishing a rationality criterion for an algebraic formal germ. Actually, rationality results for algebraic functions on the projective line have been investigated by Harbater [30], and used by Ihara [35] to study the fundamental group of some arithmetic surfaces. Ihara’s results have been extended in [11] by using Arakelov geometry on arithmetic surfaces. Our rationality argument in Section 6, based on the Hodge index theorem on arithmetic surfaces of Faltings-Hriljac, is a variation on the proof of the Lefschetz theorem on arithmetic surfaces in loc. cit..

It is a pleasure to thank A. Ducros for his helpful advice on rigid analytic geometry during the preparation of this article.

Some of the results below have been presented, in a preliminary form, during the “Arithmetic Geometry and Number Theory” conference in honor of N. Katz, in Princeton, December 2003, and have been announced in [14].

It would be difficult to acknowledge fairly the multifaceted influences of Yuri Ivanovich Manin on our work. We hope that this article will appear as a tribute, not only to his multiple contributions to algebraic geometry and number theory, but also to his global vision of mathematics, emphasizing geometric insights and analogies. The presentation of this vision in his 25th-Arbeitstagung report New directions in geometry [36] has been, since it was written, a source of wonder and inspiration to one of the authors, and we allowed ourselves to borrow the terminology “A-analytic” from the “A-geometry” programmatically discussed in [36]. It is an honour for us to dedicate this article to Yuri Ivanovich Manin.

2. Preliminary: the geometric case

The theorems we want to prove in this paper are analogues in arithmetic geometry of classical algebro-geometric results going back — at least in an implicit form — to Hartshorne, Hironaka, and Matsumura ([31],[33],[34]). Conversely, in this section we shall give short proofs of algebraic analogues of our main arithmetic theorems.

**Proposition 2.1.** — Let \( \mathcal{X} \) be a quasi-projective scheme over a field \( k \) and let \( \mathcal{P} \) be a projective connected subscheme of dimension 1 in \( \mathcal{X} \). Let \( \hat{\mathcal{C}} \) be a formal subscheme of dimension 2 in \( \mathcal{X}_{\mathcal{P}} \) admitting \( \mathcal{P} \) as a scheme of definition. Assume that \( \hat{\mathcal{C}} \) is (formally) smooth over \( k \), and that \( \mathcal{P} \) has no embedded component (of dimension 0), or equivalently, that \( \mathcal{P} \) defines a Cartier divisor in \( \hat{\mathcal{C}} \), and let \( \mathcal{N} \) be the normal bundle of the immersion \( \iota : \mathcal{P} \hookrightarrow \hat{\mathcal{C}} \), that is, the invertible sheaf \( \Theta_{\hat{\mathcal{C}}} \otimes \Theta_\mathcal{P} \) on \( \mathcal{P} \).
If the divisor $|\mathcal{P}|$ on the formal surface $\hat{C}$ is nef and positive self-intersection, then the formal surface $\hat{C}$ is algebraic, namely the Zariski-closure of $\hat{C}$ in $\mathcal{X}$ is an algebraic subvariety of dimension 2.

Let $(\mathcal{P}_i)_{i \in I}$ be the family of irreducible components of $\mathcal{P}$, and $(n_i)_{i \in I}$ their multiplicities in $\mathcal{P}$. Recall that $|\mathcal{P}|$ is said to be nef on $\hat{C}$ when $\mathcal{P}_i \cdot |\mathcal{P}| = \deg_{\mathcal{P}_i} \mathcal{N} \geq 0$ for any $i \in I$, and to have positive self-intersection if $|\mathcal{P}| \cdot |\mathcal{P}| = \sum_{i \in I} n_i \deg_{\mathcal{P}_i} \mathcal{N} \geq 0$, or equivalently, if one the non-negative integers $\deg_{\mathcal{P}_i} \mathcal{N}$ is positive. Observe that these condition are satisfied if $\mathcal{N}$ is ample on $\hat{C}$.

More general versions of the algebraicity criterion in Prop. 2.1 and of its proof below, without restriction on the dimensions of $\hat{C}$ and $\mathcal{P}$, can be found in [12], §3.3, [5], [13], Thm. 2.5 (see also [17]). Besides it will be clear from the proof that, suitably reformulated, Prop. 2.1 still holds with the smoothness assumption on $\hat{C}$ omitted; we leave this to the interested reader.

Such algebraicity criteria may also be deduced from the works of Hironaka, Matsusuma, and Hartshorne on the condition $G_2$ ([33],[34],[31]). We refer the reader to the monograph [3] for extensive discussion and references about related results concerning formal functions and projective algebraic varieties.

Note that Prop. 2.1 has consequences for the study of algebraic varieties over function fields. Let indeed $S$ be a smooth, projective, and geometrically connected curve over a field $k$. Let $f: \mathcal{X} \to S$ be a surjective map of $k$-schemes and assume that $\mathcal{P}$ is the image of a section of $f$. Let $X = \mathcal{X}_K$, $P = \mathcal{P}_K$ and $\hat{C} = \hat{C}_K$ be the generic fibers of $\mathcal{X}$, $\mathcal{P}$, and $\mathcal{C}$. Then $P$ is a $K$-rational point of $X$ and $\hat{C}$ is a germ of curve in $X$ at $P$. Observe that $\hat{C}$ is algebraic if and only if $\hat{C}$ is algebraic. Consequently, in this situation, Prop. 2.1 appears as an algebraicity criterion for a formal germ of curves $\hat{C}$ in $X$. In particular, it shows that such a formal $\hat{C}$ is algebraic if it extends to a smooth formal scheme $\hat{C}$ through $\mathcal{P}$ in $\mathcal{X}$ such that the normal bundle of $\mathcal{P}$ in $\hat{C}$ has positive degree.

Proof of Prop. 2.1. — We may assume that $\mathcal{X}$ is projective and that $\hat{C}$ is Zariski-dense in $\mathcal{X}$. We let $d = \dim \mathcal{X}$. One has obviously $d \geq 2$ and our goal is to prove the equality.

Let $\mathcal{O}(1)$ be any very ample line bundle on $\mathcal{X}$. The method of “auxiliary polynomials”, borrowed from transcendence theory, suggests the introduction of the “evaluation maps”

$$
\varphi_D: \Gamma(\mathcal{X}, \mathcal{O}(D)) \to \Gamma(\hat{C}, \mathcal{O}(D)), \quad s \mapsto s|_{\hat{C}},
$$

for positive integers $D$.

Let us denote $E_D = \Gamma(\mathcal{X}, \mathcal{O}(D))$, and for any integer $i \geq 0$, let $E_D^i$ be the set of all $s \in E_D$ such that $\varphi_D(s) = s|_{\hat{C}}$ vanishes at order at least $i$ along $\mathcal{P}$, i.e. such that the restriction of $\varphi_D(s)$ to $i\mathcal{P}$ vanishes. Since $\hat{C}$ is Zariski-dense in $\mathcal{X}$, no non-zero section
of \( \mathcal{O}(D) \) has a restriction to \( \hat{C} \) that vanishes at infinite order along \( \mathcal{P} \), and we have

\[
\bigcap_{i=0}^{\infty} E_D^i = 0.
\]

Consequently,

\[
\text{rank } E_D = \sum_{i=0}^{\infty} \text{rank}(E_D^i/E_D^{i+1}).
\]

Moreover, there is a canonical injective map of \( k \)-vector spaces

\[
E_D^i/E_D^{i+1} \rightarrow \Gamma(\mathcal{P}, \mathcal{O}(D) \otimes N^{\otimes i}),
\]

which amounts to taking the \( i \)th jet along \( \mathcal{P} \) — that is, the restriction to \( (i+1)\mathcal{P} \) of a section which vanishes at order at least \( i \). Indeed the quotient sheaf \( \mathcal{O}(D) \otimes \mathcal{O}(-i\mathcal{P})/\mathcal{O}(-i+1)\mathcal{P} \) over \( \hat{C} \) may be identified with \( \mathcal{O}(D) \otimes _{\mathcal{O}(1)} N^{\otimes i} \). Observe also that the dimension of the range of this injection satisfies an upper bound of the form

\[
\dim \Gamma(\mathcal{P}, \mathcal{O}(D) \otimes N^{\otimes i}) \leq c(D + i),
\]

valid for any non-negative integers \( D \) and \( i \).

Assume that \( E_D^i \neq 0 \) and let \( s \in E_D^i \) be any nonzero element. By assumption, \( \varphi_D(s) \) vanishes at order \( i \) along \( \mathcal{P} \), hence \( \text{div} \varphi_D(s) - i[\mathcal{P}] \) is an effective divisor on \( \hat{C} \) and its intersection number with \( [\mathcal{P}] \) is nonnegative, for \( [\mathcal{P}] \) is nef. Consequently

\[
\text{div} \varphi_D(s) \cdot [\mathcal{P}] \geq i[\mathcal{P}] \cdot [\mathcal{P}].
\]

Since

\[
\text{div} \varphi_D(s) \cdot [\mathcal{P}] = \deg_{\mathcal{P}}(\mathcal{O}(D)) = D \deg_{\mathcal{P}}(\mathcal{O}(1))
\]

and \( [\mathcal{P}] \cdot [\mathcal{P}] > 0 \) by the assumption of positive self-intersection, this implies \( i \leq aD \), where \( a := \deg_{\mathcal{P}}(\mathcal{O}(1))/[\mathcal{P}],[\mathcal{P}] \). Consequently \( E_D^i \) is reduced to 0 if \( i > aD \).

Finally, we obtain:

\[
\text{rank } E_D = \sum_{i=0}^{\infty} \text{rank}(E_D^i/E_D^{i+1}) = \sum_{i=0}^{aD} \text{rank}(E_D^i/E_D^{i+1}) \leq \sum_{i=0}^{aD} c(D + i).
\]

This proves that, when \( D \) goes to \( +\infty \),

\[
\text{rank } E_D \ll D^2.
\]

Besides

\[
\text{rank } E_D = \text{rank } \Gamma(\mathcal{X}, \mathcal{O}(D)) = D^d,
\]

by Hilbert-Samuel’s theorem. This establishes that the integer \( d \), which is at least 2, actually equals 2.

\[\square\]

**Proposition 2.2.** — Let \( f : S' \to S \) be a dominant morphism between two normal projective surfaces over a field \( k \). Let \( D \subset S \) and \( D' \subset S' \) be effective divisors such that \( f(D') = D \).

Assume that \( f|_{D'} : D' \to D \) is an isomorphism and that \( f \) induces an isomorphism \( \hat{f} : \hat{S}'_D \to \hat{S}_D \) between formal completions. If moreover \( D \) is nef and \( D \cdot D > 0 \), then \( f \) is birational.
Recall that $D$ is said to be nef if, for any effective divisor $E$ on $S$ the (rational) intersection number $D \cdot E$ is non-negative.

**Proof.** — By hypothesis, $f$ is étale in a neighborhood of $D'$. If $\deg(f) > 1$, one can therefore write $f^*D = D' + D''$, where $D''$ is a non-zero effective Cartier divisor on $S$ which is disjoint from $D'$. Now, $f^*D$ is a nef divisor on $S'$ such that $f^*D \cdot f^*D = \deg(f)D \cdot D > 0$. As a classical consequence of Hodge’s index theorem (see [23], [41]) and also [11], prop. 2.2), the effective divisor $f^*D$ is numerically connected, hence connected. This contradicts the decomposition $f^*D = D' \sqcup D''$. 

**Proposition 2.3.** — Let $\mathcal{I}$ be a smooth projective connected surface over a perfect field $k$. Let $\mathcal{D}$ be a smooth projective connected curve in $\mathcal{I}$. If the divisor $|\mathcal{D}|$ on $\mathcal{I}$ is big and nef, then any formal rational function along $\mathcal{D}$ is defined by a (unique) rational function on $\mathcal{I}$. In other words, one has an isomorphism of fields

$$k(\mathcal{I}) \xrightarrow{\sim} \Gamma(\mathcal{D}, \text{Frac} \mathcal{O}_{\mathcal{D}}).$$

**Proof.** — Let $\varphi$ be any formal rational function along $\mathcal{D}$. We may introduce a sequence of blowing-ups of closed points $v: \mathcal{I}' \to \mathcal{I}$ such that $\varphi' = v^*\varphi$ has no point of indetermination and may be seen as a map (of formal $k$-schemes) $\mathcal{I}' \to \mathbb{P}_k^1$, where $\mathbb{P}^1 = v^*\mathcal{D}$. Let us consider the graph $\text{Gr} \varphi'$ of $\varphi'$ in $\mathcal{I}' \times \mathbb{P}_k^1$. This is a formally smooth 2-dimensional formal scheme, admitting the graph of $\psi_{|\mathcal{D}'}: \mathcal{D}' \to \mathbb{P}_k^1$ as a scheme of definition, and the morphism $\varphi'$ defines an isomorphism of formal schemes

$$\psi' := (\text{Id}, \varphi): \mathcal{I}' \to \text{Gr} \varphi'.$$

Like the divisor $\mathcal{D}$ in $\mathcal{I}$, its inverse image $\mathcal{D}'$ in $\mathcal{I}'$ is nef and has positive self-intersection. Prop. 2.1 therefore implies that $\text{Gr} \varphi'$ is algebraic in $\mathcal{I}' \times \mathbb{P}_k^1$. In other words, $\varphi'$ is an algebraic function.

To establish its rationality, let us introduce the Zariski closure $\Gamma$ of the graph of $\text{Gr} \varphi'$ in $\mathcal{I}' \times \mathbb{P}_k^1$, the projections $\text{pr}_1: \Gamma \to \mathcal{I}'$ and $\text{pr}_2: \Gamma \to \mathbb{P}_k^1$, and the normalization $n: \tilde{\Gamma} \to \Gamma$ of $\Gamma$. Consider also the Cartier divisor $\mathcal{D}'_k$ (resp. $\mathbb{P}_k^1$) defined as the inverse image $\text{pr}_1^*\mathcal{D}'$ (resp. $n^*\mathbb{P}_k^1$) of $\mathcal{D}'$ in $\Gamma$ (resp. $\tilde{\Gamma}$). The morphisms $n$ and $\text{pr}_1$ define morphism of formal completions:

$$\tilde{\Gamma}_{\mathcal{I}'} \xrightarrow{n} \tilde{\Gamma} \xrightarrow{\text{pr}_1} \mathcal{I}'_{\mathcal{D}}.$$

The morphism $\psi$ may be seen a section of $\tilde{\mathcal{D}}_k$; by normality of $\tilde{\mathcal{D}}_k$, it admits a factorization through $\tilde{h}$ of the form $\psi' = \tilde{h} \circ \tilde{\psi}$, for some uniquely determined morphism of $k$-formal schemes $\tilde{\psi}: \tilde{\mathcal{D}}_k \to \tilde{\Gamma}_{\mathcal{I}'}$. This morphism $\tilde{\psi}$ is a section of $\tilde{\mathcal{D}}_k \circ \tilde{h}$. Therefore the (scheme theoretic) image $\tilde{\psi}(\mathcal{D}')$ defines a (Cartier) divisor in $\tilde{\Gamma}$ such that

$$(f: S' \to S, D', D) = (\text{pr}_1 \circ n: \tilde{\Gamma} \to \mathcal{I}', \mathcal{D}', \mathcal{D}')$$

satisfy the hypotheses of Prop. 2.2. Consequently the morphism $\text{pr}_1 \circ n$ is birational and $\varphi'$ (resp. $\varphi$) is the restriction of a rational function on $\mathcal{I}'$ (resp. on $\mathcal{I}$), namely $\text{pr}_2 \circ (\text{pr}_1 \circ n)^{-1}$. 

The uniqueness of this rational function follows from the Zariski density of the formal neighborhood of $\mathcal{P}$ in $\mathcal{I}$.

\[\square\]

**Remark 2.4.** — In the terminology of Hironaka and Matsumura [34], the last proposition asserts that $\mathcal{P}$ is $G_3$ in $\mathcal{I}$, and has been established by Hironaka in [33]. Hartshorne observes in [32] (Prop. 4.3, and Remark p. 123) that Prop. 2.2 holds more generally under the assumption that $\mathcal{P}$ is $G_3$ in $\mathcal{I}$. Our approach to Prop. 2.2 and Prop. 2.3 follows an order opposite to the one in [33] and [32], and actually provides a simple proof of [32], Prop. 4.3.

3. $A$-analyticity of formal curves

3.A. Size of smooth formal curves over $p$-adic fields

In this Section, we briefly recall some definitions and results from [12]. Let $K$ be field equipped with some complete ultrametric absolute value $|\cdot|$ and assume that its valuation ring $R$ is a discrete valuation ring. Let also $\overline{K}$ be an algebraic closure of $K$. We shall still denote $|\cdot|$ the non-archimedean absolute value on $\overline{K}$ that extends the absolute value $|\cdot|$ on $K$.

For any positive real number $r$, we define the norm $\|g\|_r$ of a formal power series $g = \sum_{I \in \mathbb{N}^N} a_I X^I \in K[[X_1, \ldots, X_N]]$ by the formula

$$\|g\|_r = \sup_I |a_I| r^{|I|};$$

it belongs to $\mathbb{R}_+ \cup \{\infty\}$. The power series $g$ such that $\|g\|_r < \infty$ are precisely those which are convergent and bounded on the open $N$-ball of radius $r$ in $\overline{K}^N$.

The group $G_{\text{for},K} := \text{Aut}(\mathcal{A}_K^N)$ of automorphisms of the formal completion of $\mathcal{A}_K^N$ at 0 may be identified with the set of all $N$-tuples $f = (f_1, \ldots, f_N)$ of power series in $K[[X_1, \ldots, X_N]]$ such that $f(0) = 0$ and $Df(0) := \left(\frac{\partial f_j}{\partial X_i}(0)\right)$ belongs to $GL_N(K)$. We consider its following subgroups:

- the subgroups $G_{\text{for}}$ consisting of all elements $f \in G_{\text{for},K}$ such that $Df(0) \in GL_N(R)$;
- the subgroup $G_{\text{an},K}$ consisting of those $f = (f_1, \ldots, f_N)$ such that, for each $j$, $f_j$ has a positive radius of convergence;
- $G_{\text{an}} := G_{\text{an},K} \cap G_{\text{for}}$;
- for any positive real number $r$, the subgroup $G_{\text{an},r}$ of $G_{\text{an}}$ consisting of all $N$-tuples $f = (f_1, \ldots, f_N)$ such that $\|f_j\|_r \leq r$ for each $j$. This subgroup may be identified with the group of all analytic automorphisms, preserving the origin, of the open $N$-dimensional ball of radius $r$.

One has the inclusion $G_{\text{an},r'} \subset G_{\text{an},r}$ for any $r' > r > 0$, and the equalities

$$\bigcup_{r > 0} G_{\text{an},r} = G_{\text{an}} \quad \text{and} \quad G_{\text{an},1} = \text{Aut}(\mathcal{A}_K^N).$$

It is straightforward that a formal subscheme $\hat{V}$ of $\mathcal{A}_K^N$ is smooth of dimension $d$ iff there exists $\varphi \in G_{\text{for},K}$ such that $\varphi^* \hat{V}$ is the formal subscheme $\mathcal{A}_K^d \times \{0\}$ of $\mathcal{A}_K^N$, when
this holds, one can even find such a \( \phi \) in \( G_{\text{for}} \). Moreover such a smooth formal subscheme \( \hat{V} \) is \( K \)-analytic iff one can find \( \phi \) as above in \( G_{\text{an,K}} \), or equivalently in \( G_{\text{an}} \).

Let \( \mathcal{X} \) be a flat quasi-projective \( R \)-scheme, and \( X = \mathcal{X} \otimes_R K \) its generic fibre. Let \( \mathcal{P} \in \mathcal{X}(R) \) be an \( R \)-point, and let \( P \in X(K) \) be its restriction to \( \text{Spec} \, K \). In [12], §3.1.1, to any smooth formal scheme \( \hat{V} \) of dimension \( d \) in \( \hat{X}_P \), we associated its size \( S_{\mathcal{X}}(\hat{V}) \) with respect to the model \( \mathcal{X} \) of \( X \). It is a number in \([0,1]\) whose definition and basic properties may be summarized in the following statement:

**Theorem 3.1.** — There is a unique way to attach a number \( S_{\mathcal{X}}(\hat{V}) \) in \([0,1]\) to any such data \((\mathcal{X}, \mathcal{P}, \hat{V})\) so that the following properties hold:

a) if \( \mathcal{X} \to \mathcal{X}' \) is an immersion, then \( S_{\mathcal{X}'}(\hat{V}') = S_{\mathcal{X}}(\hat{V}) \) (invariance under immersions);

b) for any two triples \((\mathcal{X}, \mathcal{P}, \hat{V})\) and \((\mathcal{X}', \mathcal{P}', \hat{V}')\) as above, if there exists an \( R \)-morphism \( \phi: \mathcal{X} \to \mathcal{X}' \) mapping \( \mathcal{P} \) to \( \mathcal{P}' \), étale along \( \mathcal{P} \), and inducing an isomorphism \( \hat{V} \cong \hat{V}' \), then \( S_{\mathcal{X}'}(\hat{V}') = S_{\mathcal{X}}(\hat{V}) \) (invariance by étale localization);

c) if \( \mathcal{X} = A^d_N \) is the affine space over \( R \) and \( \mathcal{P} = (0,\ldots,0) \), then \( S_{\mathcal{X}}(\hat{V}) \) is the supremum in \([0,1]\) of the real numbers \( r \in (0,1] \) for which there exists \( f \in G_{\text{an},r} \) such that \( f^* \hat{V} = \hat{A}^d_0 \times \{0\} \) (normalization).

As a straightforward consequence of these properties of the size, we obtain:

**Proposition 3.2.** — A smooth formal subscheme \( \hat{V} \) in \( \hat{X}_P \) is \( K \)-analytic if and only if its size \( S_{\mathcal{X}}(\hat{V}) \) is a positive real number.

**Proposition 3.3.** — Let \( \mathcal{X}, \mathcal{P}, \) and \( \hat{V} \) be as above and assume that there exists a smooth formal \( R \)-subscheme \( \hat{V} \subset \hat{X}_\mathcal{P} \) such that \( \hat{V} = \mathcal{V}_K \). Then \( S_{\mathcal{X}}(\hat{V}) = 1 \).

The remainder of this section is devoted to further properties of the size.

**Proposition 3.4.** — The size is invariant under isometric extensions of valued fields (complete with respect to a discrete valuation).

**Proof.** — It suffices to check this assertion in the case of a smooth formal subscheme \( \hat{V} \) through the origin of the affine space \( A^d_N \). By its very definition, the size cannot decrease under extensions of the base field.

To show that it cannot increase either, let us fix an isomorphism of \( K \)-formal schemes

\[
\xi = (\xi_1,\ldots,\xi_N) : \hat{A}^d_0 \xymatrix{\ar[r] & \hat{V} \ar[r] & \hat{A}^d_0}
\]

given by \( N \) power series \( \xi_i \in K[[T_1,\ldots,T_d]] \) such that \( \xi_1(0) = \cdots = \xi_N(0) = 0 \), and observe that, for any \( N \)-tuple \( g = (g_1,\ldots,g_N) \) of series in \( K[[X_1,\ldots,X_N]] \), the following two conditions are equivalent:

- (i) \( g \) belongs to \( G_{\text{for},K} \) and \( (g^{-1})^* \hat{V} = \hat{A}^d_0 \times \{0\} \);
- (ii) \( g_1(0) = \cdots = g_N(0) = 0 \), \( g_{d+1}(\xi_1,\ldots,\xi_N) = \cdots = g_N(\xi_1,\ldots,\xi_N) = 0 \), and \( \left( \frac{\partial g_i}{\partial X_j}(0) \right) \) belongs to \( GL_N(K) \).
Let $K'$ be a valued field, satisfying the same condition as $K$, that contains $K$ and whose absolute value restricts to the given one on $K$. Let $R'$ be its valuation ring. We shall denote $G^r_{\text{for}}, G^r_{\text{an}}, G^r_{\text{an},r}, \ldots$ the analogues of $G_{\text{for}}, G_{\text{an}}, G_{\text{an},r}, \ldots$ defined by replacing the valued field $K$ by $K'$. Recall that there exists an "orthogonal projection" from $K'$ to $K$, namely a $K$-linear map $\lambda : K' \to K$ such that $|\lambda(a)| \leq |a|$ for any $a \in K'$ and $\lambda(a) = a$ for any $a \in K$; see for instance [28], p. 58, Corollary (2.3).

Let \( \hat{V}' = \hat{V}_{K'} \) be the formal subscheme of \( \hat{A}^N_{K'} \) deduced from $\hat{V}$ by the extension of scalars $K \hookrightarrow K'$, and let $r$ be an element in $]0, S_{\hat{A}^N_{K'}}(\hat{V}')[. By the very definition of the size, there exists some $g' = (g'_1, \ldots, g'_N)$ in $G^r_{\text{an},r}$ such that $(g'^{-1})^* \hat{V} = \hat{A}^d_0 \times \{0\}$. Since the tangent space at the origin of $\hat{V}'$ is defined over $K$, by composing $g'$ with a suitable element in $GL_N(R')$, we may even find $g'$ such that $Dg'(0)$ belongs to $GL_N(R)$. Then the series $g_i := \lambda \circ g'_i$, deduced from the series $g'_i$ by applying the linear map $\lambda$ to their coefficients, satisfy $g_i(0) = 0$, $(\partial g_i / \partial X_j)(0) = (\partial g'_i / \partial X_j)(0)$ and $\|g_i\|_r \leq \|g'_i\|_r$. Therefore $g := (g_1, \ldots, g_N)$ is an element of $G_{\text{an},r}$. Moreover, from the equivalence of conditions (i) and (ii) above and its analogue with $K'$ instead of $K$, we derive that $g$ satisfies $(g^{-1})^* \hat{V} = \hat{A}^d_0 \times \{0\}$. This shows that $S_{\hat{A}^N_K}(\hat{V}) \geq r$ and establishes the required inequality $S_{\hat{A}^N_{K'}}(\hat{V}) \geq S_{\hat{A}^N_{K'}}(\hat{V})$.

The next proposition relates sizes, radii of convergence, and Newton polygons.

**Proposition 3.5.** — Let $\varphi \in K[[X]]$ be a power series such that $\varphi(0) = 0$ and $\varphi'(0) \in R$, and let $\acute{C}$ be its graph, namely the formal subscheme of $\hat{A}^2_0$ defined by the equation $x_2 = \varphi(x_1)$.

1) The radius of convergence $\rho$ of $\varphi$ satisfies

$$\rho \geq S_{\hat{A}^2_0}(\acute{C}).$$

2) Suppose that $\rho$ is positive and that $\varphi'(0)$ is a unit in $R$. Then

$$S_{\hat{A}^2_0}(\acute{C}) = \min(1, \exp \lambda_1),$$

where $\lambda_1$ denotes the first slope of the Newton polygon of the power series $\varphi(x)/x$.

Recall that, if $\varphi = \sum_{i \geq 1} c_i T^i$, under the hypothesis in 2), we have:

$$\lambda_1 := \inf_{i \geq 1} - \frac{\log|c_{i+1}|}{i} \leq \lim_{i \to +\infty} \inf_{i} - \frac{\log|c_{i+1}|}{i} = \log \rho.$$ 

Moreover $\exp \lambda_1$ is the supremum of the numbers $r \in ]0, \rho[$ such that, for any $t \in \overline{K}$ satisfying $|t| < r$, we have $|\varphi(t)| = |t|$.

**Proof.** — Let $r$ be a positive real number such that $r < S_{\hat{A}^2_0}(\acute{C})$. By assumption, there are power series $f_1$ and $f_2 \in K[[X_1, X_2]]$ such that $f = (f_1, f_2)$ belongs to $G_{\text{an},r}$ and such that $f^* \acute{C} = \hat{A}^2_0 \times \{0\}$. This last condition implies (actually is equivalent to) the identity in $K[[T]]$:

$$f_2(T, 0) = \varphi(f_1(T, 0)).$$

Let us write $f_1(T, 0) = \sum_{i \geq 1} a_i T^i$, $f_2(T, 0) = \sum_{i \geq 1} b_i T^i$, and $\varphi(X) = \sum_{i \geq 1} c_i X^i$. 

One has $b_1 = c_1 a_1$ and $c_1 = \varphi'(0)$ belongs to $R$ by hypothesis. Moreover, the first column of the matrix $Df(0)$ is $(a_1) = a_1 \left( \begin{array}{c} 1 \\ c_1 \end{array} \right)$. Since $Df(0)$ belongs to $\text{GL}_2(R)$ and $c_1$ to $R$, this implies that $a_1$ is a unit in $R$. Then, looking at the expansion of $f_1(T,0)$ (which satisfies $\|f_1(T,0)\|_r \leqslant r$), we see that $|f_1(t,0)| = |t|$ for any $t \in \overline{K}$ such that $|t| < r$. Consequently, if $g \in K[[T]]$ denotes the reciprocal power series of $f_1(T,0)$, then $g$ converges on the open disc of radius $r$ and satisfies $|g(t)| = |t|$ for any $t \in \overline{K}$ such that $|t| < r$.

The identity in $K[[T]]$

$$\varphi(T) = \varphi(f_1(g(T),0)) = f_2(g(T),0)$$

then shows that the radius of convergence of $\varphi$ is at least $r$. This establishes 1).

Let us now assume that $\rho$ is positive and that $\varphi'(0)(= c_1)$ is a unit of $R$. Then $b_1 = a_1 c_1$ also is a unit and similarly, we have $|f_2(t,0)| = |t|$ for any $t \in \overline{K}$ such that $|t| < r$. This implies that $|\varphi(t)| = |t|$ for any such $t$. This shows that $\exp \lambda_1 \geqslant S_{\lambda_1}^G(\hat{C})$.

To complete the proof of 2), observe that the element $f$ of $G_{\text{an}}$ defined as $f(T_1, T_2) = (T_1 + T_2, \varphi(T_1))$ satisfies $f^* \hat{C} = \hat{A}^1 \times \{0\}$ and belongs to $G_{\text{an},r}$ for any $r$ in $|0, \min(1, \exp \lambda_1)|$. □

Observe that for any non zero $a \in R$, the series $\varphi(T) = T/|a-T|$ has radius of convergence $\rho = |a|$ while the size of its graph $\hat{C}$ is 1 (observe that $f(T_1, T_2) := (aT_1 + T_2, T_1/(1-T_1))$ satisfies $f^* \hat{C} = \hat{A}^1 \times \{0\}$). Taking $|a| < 1$, this shows that the size of the graph of a power series $\varphi$ can be larger than its radius of convergence when the assumption $\varphi'(0) \in R$ is omitted.

As an application of the second assertion in Prop.3.5, we obtain that, when $K$ is a $p$-adic field, the size of the graph of $\log(1+x)$ is equal to $|p|^{1/(p-1)}$. Considering this graph as the graph of the exponential power series with axes exchanged, this also follows from the first assertions of Prop.3.5 and Prop. 3.6 below.

Finally, let us indicate that, by analyzing the construction à la Cauchy of local solutions of analytic ordinary differential equations, one may establish the following lower bounds on the size of a formal curve obtained by integrating an algebraic one-dimensional foliation over a $p$-adic field (cf. [13], Prop. 4.1):

**Proposition 3.6.** — Assume that $K$ is a field of characteristic 0, and that its residue field $k$ has positive characteristic $p$. Assume also that $\mathcal{X}$ is smooth over $R$ in a neighborhood of $\mathcal{P}$. Let $\mathcal{F} \subset T_{\mathcal{X}|R}$ be a rank 1 subbundle and let $\hat{C}$ be the integral curve through $P$ of the one-dimensional foliation $F = \mathcal{F}_R$. Then

$$S_{\mathcal{X}}(\hat{C}) \geqslant |p|^{1/(p-1)}.$$  

If moreover $K$ is absolutely unramified (that is, if the maximal ideal of $R$ is $pR$) and if the one-dimensional subbundle $\mathcal{F}_k \subset T_{\mathcal{X}_k}$ is closed under $p$-th power, then $S_{\mathcal{X}}(\hat{C}) \geqslant |p|^{1/p(p-1)}$.

3.B. A-analyticity of formal curves in algebraic varieties over number fields

Let $K$ be a number field and let $R$ denote its ring of integers. For any maximal ideal $p$ of $R$, let $|\cdot|_p$ denote the $p$-adic absolute value, normalized by the condition
$|\pi|_p = \left(\#(R/p)\right)^{-1}$ for any uniformizing element $\pi$ at $p$. Let $K_p$ and $R_p$ be the $p$-adic completions of $K$ and $R$, and $F_p := R/p$ the residue field of $p$.

In this Section, we consider a quasi-projective algebraic variety $X$ over $K$, a rational point $P$ in $X(K)$, and a smooth formal curve $\hat{C}$ in $\hat{X}$.

It is straightforward that, if $N$ denotes a sufficiently divisible positive integer, there exists a model $\tilde{X}$ of $X$, quasi-projective over $\mathbb{R}[[1/N]]$, such that $P$ extends to a point $\tilde{P}$ in $\tilde{X}(R[[1/N]])$. Then, for any maximal ideal $p$ not dividing $N$, the size $S_{\hat{X}R_p}(\hat{C}_{K_p})$ is a well-defined real number in $[0,1]$.

**Definition 3.7.** — We will say that the formal curve $\hat{C}$ in $X$ is $A$-analytic if the following conditions are satisfied:

(i) for any place $v$ of $K$, the formal curve $\hat{C}_{K_v}$ is $K_v$-analytic;

(ii) the infinite product $\prod_{p|N} S_{\hat{X}R_p}(\hat{C}_{K_p})$ converges to a positive real number.

Condition (ii) asserts precisely that the series with non-negative terms

$$\sum_{p|N} \log S_{\hat{X}R_p}(\hat{C}_{K_p})^{-1}$$

is convergent.

Observe that the above definition does not depend on the choices required to formulate it. Indeed, condition (i) does not depend on any choice. Moreover, if condition (i) holds and if $N'$ is any positive multiple of $N$, condition (ii) holds for $(N,\mathcal{X},\mathcal{P})$ if and only if it holds for $(N',\mathcal{X}_{R[1/N']},\mathcal{P}_{R[1/N']})$. Moreover, for any two such triples $(N_1,\mathcal{X}_1,\mathcal{P}_1)$ and $(N_2,\mathcal{X}_2,\mathcal{P}_2)$, there is a positive integer $M$, multiple of both $N_1$ and $N_2$, such that the models $(\mathcal{X}_1,\mathcal{P}_1)$ and $(\mathcal{X}_2,\mathcal{P}_2)$ of $(X,P)$ become isomorphic over $\mathbb{R}[1/M]$. This shows that, when (i) is satisfied, conditions (ii) for any two triples $(N,\mathcal{X},\mathcal{P})$ are indeed equivalent.

It follows from the properties of the size recalled in Prop. 3.1 that $A$-analyticity is invariant under immersions and compatible to étale localization.

As a consequence of Prop. 3.2 and 3.3, we also have:

**Proposition 3.8.** — Let $\hat{C}$ be a smooth formal curve which is $K_v$-analytic for any place $v$ of $K$. Assume that $\hat{C}$ extends to a smooth formal curve $\hat{C} \hookrightarrow \mathcal{X}$ over $R[1/N]$, for some $N \geq 1$. Then $\hat{C}$ is $A$-analytic.

Indeed, these conditions imply that the size of $\hat{C}$ at almost every finite place of $K$ is equal to 1, while being positive at every places.

As observed in substance by Eisenstein [22], any algebraic smooth formal curve satisfies the hypothesis of Prop. 3.8. Therefore:

**Corollary 3.9.** — If the smooth formal curve $\hat{C}$ is algebraic, then it is $A$-analytic.

The invariance of size under extensions of valued fields established in Prop. 3.4 easily implies that, for any number field $K'$ containing $K$, the smooth formal curve $\hat{C}' := \hat{C}_{K'}$ in $X_{K'}$ deduced from $\hat{C}$ by the extension of scalars $K \hookrightarrow K'$ is $A$-analytic iff $\hat{C}$ is $A$-analytic.

Let $\varphi \in K[[X]]$ be any formal power series, and let $P := (0,\varphi(0))$. From the inequality in Prop. 3.5, 1), between the convergence radius of a power series and the size of its
It follows that the $A$-analyticity of the graph $\hat{C}$ of $\varphi$ in $\mathbb{A}^2_p$ implies that the convergence radii $R_v$ of $\varphi$ at the places $v$ of $K$ satisfy the so-called Bombieri’s condition

$$\prod_v \min(1, R_v) > 0,$$

or equivalently

$$\sum_v \log^+ R_v^{-1} < +\infty.$$

However the converse does not hold, as can be seen by considering $\varphi(X) = \log(1 + X)$, that satisfies the Bombieri’s condition (since all the $R_v$ equal 1), but is not $A$-analytic (its $p$-adic size is $|p|^{1/(p-1)}$ and the infinite series $\sum \frac{1}{p-1} \log p$ diverges).

Let us conclude this section by a brief discussion of the relevance of $A$-analyticity in the arithmetic theory of differential equations.

Assume that $X$ is smooth over $K$, that $F$ is sub-vector bundle of rank one in the tangent bundle $T_X$ (defined over $K$), and that $\hat{C}$ is the formal leaf at $P$ the one-dimensional algebraic foliation on $X$ defined by $F$. By a model of $(X, F)$ over $R[1/N]$, we mean the data of a scheme $\mathcal{X}$ quasi-projective and smooth over $\text{Spec} R$, of a subsheaf $\mathcal{F}$ of $T_{\mathcal{X}/R}$, and of an isomorphism $X = \mathcal{X} \otimes K$ inducing an isomorphism $F = \mathcal{F} \otimes K$. Such models clearly exist if $N$ is sufficiently divisible. Let us choose one of them $(\mathcal{X}', \mathcal{F})$. We say that the foliation $F$ satisfies the Grothendieck-Katz condition if for almost every maximal ideal $p \subset R$, the subsheaf $F_{\mathcal{F}_{p}}$ of $T_{\mathcal{X}'_p/R_p}$ is closed under $p$-th powers, where $p$ denotes the characteristic of $F_p$. As above, this condition does not depend on the choice of the model $(\mathcal{X}', \mathcal{F})$.

Proposition 3.10. — With the above notation, if $F$ satisfies the Grothendieck-Katz condition, then its formal integral curve $\hat{C}$ is $A$-analytic.

Proof. — It follows from Cauchy’s theory of formal and analytic ordinary differential equations over local fields that the formal curve $\hat{C}$ is $K_v$-analytic for any place $v$ of $K$.

After possibly increasing $N$, we may assume that $P$ extends to a section $\mathcal{P}$ in $\mathcal{X}'(R[1/N])$. For each maximal ideal $p \subset R$ which is unramified over a prime number $p$, and such that $\mathcal{F}_{p}$ is closed under $p$-th power, Prop. 3.6 show that the $p$-adic size of $\hat{C}$ is at least $|p|^{1/(p-1)}$. When $F$ satisfies the Grothendieck-Katz condition, this inequality holds for almost all maximal ideals of $R$. Since the series over primes $\sum p \frac{1}{p-1} \log p$ converges, this implies the convergence of the series $\sum_{p \nmid N} \log S_{\mathcal{X}_p}(\hat{C}_{p})^{-1}$ and consequently the $A$-analyticity of $\hat{C}$.

4. Analytic curves in algebraic varieties over local fields and canonical semi-norms

4.A. Consistent sequences of norms

Let $K$ be a local field, $X$ a projective scheme over $K$, and $L$ a line bundle over $X$.

We may consider the following natural constructions of sequences of norms on the spaces of sections $\Gamma(X, L^\otimes n)$:
(1) When $K = \mathbb{C}$ and $X$ is reduced, we may choose an arbitrary continuous norm $\| \cdot \|_L$ on the $\mathbb{C}$-analytic line bundle $L_{\text{an}}$ defined by $L$ on the compact and reduced complex analytic space $X(\mathbb{C})$. Then, for any integer $n$, the space of algebraic regular sections $\Gamma(X, L^\otimes n)$ may be identified with a subspace of the space of continuous sections of $L_{\text{an}}^\otimes n$ over $X(\mathbb{C})$. It may therefore be equipped with the restriction of the $L^\infty$-norm, defined by:

$$
\| s \|_{L^\infty,n} := \sup_{x \in X(\mathbb{C})} \| s(x) \|_{L^\otimes n}
$$

where $\| \cdot \|_{L^\otimes n}$ denotes the continuous norm on $L_{\text{an}}^\otimes n$ deduced from $\| \cdot \|_L$ by taking the $n$-th tensor power.

This construction admits a variant where, instead of the sup-norms (4.1), we may consider the $L^n$-norms defined by using some "Lebesgue measure" (cf. [12], 4.1.3, and [42], Théorème 3.10).

(2) When $K = \mathbb{R}$ and $X$ is reduced, we may choose a continuous norm on $L_\mathbb{C}$ that is invariant under complex conjugation. The previous constructions define complex norms on the complex vector spaces $\Gamma(X, L^\otimes n)$ which are invariant under complex conjugation, and by restriction, real norms on the real vector spaces $\Gamma(X, L^\otimes n)$.

(3) When $K$ is a $p$-adic field, with ring of integers $\mathfrak{O}$, we may choose a pair $(\mathcal{X}, \mathcal{L})$, where $\mathcal{X}$ is a projective flat model of $X$ over $\mathfrak{O}$, and $\mathcal{L}$ a line bundle over $\mathcal{X}$ extending $L$. Then, for any integer $n$, the $\mathfrak{O}$-module $\Gamma(\mathcal{X}, \mathcal{L}^\otimes n)$ is (torsion-)free of finite rank and may be identified with an $\mathfrak{O}$-lattice in the $K$-vector space $\Gamma(X, L^\otimes n)$, and consequently defines a norm on the latter — namely, the norm $\| \cdot \|_n$ such that a section $s \in \Gamma(X, L^\otimes n)$ satisfies $\| s \|_n \leq 1$ iff $s$ extends to a section of $\mathcal{L}^\otimes n$ over $\mathcal{X}$.

(4) Construction (1) can be used when $K$ is a $p$-adic field. Let $\| \cdot \|$ be a metric on $L$ (see Appendix A for basic definitions concerning metrics in the $p$-adic setting). For any integer $n$, the space $\Gamma(X, L^\otimes n)$ admits a $L^\infty$-norm, defined for any $s \in \Gamma(X, L^\otimes n)$ by $\| s \|_{L^\infty,n} := \sup_{x \in X(\mathcal{O})} \| s(x) \|$. When the metric of $L$ is defined by a model $\mathcal{L}$ of $L$ on a normal projective model $\mathcal{X}$ of $X$ on $R$, then this norm coincides with that defined by construction (3) (see, e.g., [44], prop. 1.2).

For any given $K$, $X$, and $L$ as above, we shall say that two sequences $(\| \cdot \|_n)_{n \in \mathbb{N}}$ and $(\| \cdot \|'_n)_{n \in \mathbb{N}}$ of norms on the finite dimensional $K$-vector spaces $(\Gamma(X, L^\otimes n))_{n \in \mathbb{N}}$ are equivalent when, for some positive constant $C$ and any positive integer $n$,

$$
C^{-n} \| \cdot \|'_n \leq \| \cdot \|_n \leq C^n \| \cdot \|'_n.
$$

One easily checks that, for any given $K$, $X$, and $L$, the above constructions provide sequences of norms $(\| \cdot \|_n)_{n \in \mathbb{N}}$ on the sequence of spaces $(\Gamma(X, L^\otimes n))_{n \in \mathbb{N}}$ which remain equivalent when the auxiliary data (models, norms on $L$, ...) change. (For the comparison of the $L^2$ and $L^\infty$ norms in the archimedean case, see notably [42], Théorème 3.10.)
A sequence of norms on the spaces $\Gamma(X, L^{\otimes n})$ that is equivalent to one (or, equivalently, to any) of the sequences thus constructed will be called consistent. This notion immediately extends to sequences $(\|\cdot\|_n)_{n \geq n_0}$ of norms on the spaces $\Gamma(X, L^{\otimes n})$, defined only for $n$ large enough.

When the line bundle $L$ is ample, consistent sequences of norms are also provided by additional constructions. Indeed we have:

**Proposition 4.2.** — Let $K$ be a local field, $X$ a projective scheme over $K$, and $L$ an ample line bundle over $X$. Let moreover $Y$ be a closed subscheme of $X$, and assume $X$ and $Y$ reduced when $K$ is archimedean.

For any consistent sequence of norms $(\|\cdot\|_n)_{n \in \mathbb{N}}$ on $(\Gamma(X, L^{\otimes n}))_{n \in \mathbb{N}}$, the quotient norms $(\|\cdot\|'_n)_{n \in \mathbb{N}}$ on the spaces $(\Gamma(Y, L^{\otimes n}))_{n \geq n_0}$, deduced from the norms $\|\cdot\|_n$ by means of the restriction maps $\Gamma(X, L^{\otimes n}) \rightarrow \Gamma(Y, L^{\otimes n})$ — which are surjective for $n \geq n_0$ large enough since $L$ is ample — constitute a consistent sequence.

When $K$ is archimedean, this is proved in [13], Appendix, by introducing a positive metric on $L$, as a consequence of Grauert’s finiteness theorem for pseudo-convex domains applied to the unit disk bundle of $L^\vee$ (see also [42]).

When $K$ is a $p$-adic field with ring of integers $\mathcal{O}$, Proposition 4.2 follows from the basic properties of ample line bundles over projective $\mathcal{O}$-schemes. Let indeed $\mathcal{X}$ be a projective flat model of $X$ over $\mathcal{O}$, $\mathcal{L}$ an ample line bundle on $\mathcal{X}$, $\mathcal{Y}$ the closure of $Y$ in $\mathcal{X}$, and $\mathcal{I}_Y$ the ideal sheaf of $Y$. If the positive integer $n$ is large enough, then the cohomology group $H^1(\mathcal{Y}, \mathcal{I}_Y \cdot L^{\otimes n})$ vanishes, and the restriction morphism $\Gamma(\mathcal{X}, L^{\otimes n}) \rightarrow \Gamma(\mathcal{Y}, L^{\otimes n})$ is therefore surjective. Consequently, the norm on $\Gamma(\mathcal{Y}, L^{\otimes n})$ attached to the lattice $\Gamma(\mathcal{Y}, L^{\otimes n})$ is the quotient of the one on $\Gamma(X, L^{\otimes n})$ attached to $\Gamma(\mathcal{X}, L^{\otimes n})$.

Let $E$ be a finite dimensional vector space over the local field $K$, equipped with some norm, supposed to be euclidean or hermitian in the archimedean case. This norm induces similar norms on the tensor powers $E^{\otimes n}$, $n \in \mathbb{N}$, hence — by taking the quotient norms — on the symmetric powers $\text{Sym}^n E$. If $X$ is the projective space $\text{Proj} \text{Sym} (E)$ and $L$ the line bundle $\mathcal{O}(1)$, then the canonical isomorphisms $\text{Sym}^n E \cong \Gamma(X, L^{\otimes n})$ allow one to see these norms as a sequence of norms on $(\Gamma(X, L^{\otimes n}))_{n \in \mathbb{N}}$. One easily checks that this sequence is consistent. (This is straightforward in the $p$-adic case. When $K$ is archimedean, this follows for instance from [15], Lemma 4.3.6.)

For any closed subvariety $Y$ in $\text{Proj} (E)$ and any $n \in \mathbb{N}$, we may consider the commutative diagram of $K$-linear maps:

$$
\begin{array}{ccc}
\text{Sym}^n E & \longrightarrow & \text{Sym}^n \Gamma(\mathcal{P}(E), \mathcal{O}(1)) \\
\downarrow & & \downarrow \alpha_n \\
\text{Sym}^n \Gamma(\mathcal{Y}, \mathcal{O}(1)) & \longrightarrow & \Gamma(\mathcal{Y}, \mathcal{O}(n)) \quad \beta_n
\end{array}
$$

where the vertical maps are the obvious restriction morphisms. The maps $\alpha_n$, and consequently $\beta_n$, are surjective if $n$ is large enough.

Together with Proposition 4.2, these observations yield the following corollary:
Corollary 4.3. — Let $K$, $E$, and $Y$ a closed subscheme of $\mathbf{P}(E)$ be as above. Assume that $Y$ is reduced if $K$ is archimedean. Let us choose a norm on $E$ (resp. on $\Gamma(Y, \mathcal{O}(1))$) and let us equip $\text{Sym}^n E$ (resp. $\text{Sym}^n \Gamma(Y, \mathcal{O}(1))$) with the induced norm, for any $n \in \mathbb{N}$.

Then the sequence of quotient norms on $\Gamma(Y, \mathcal{O}(n))$ defined for $n$ large enough by means of the surjective morphisms $\alpha_n$: $\text{Sym}^n E \to \Gamma(Y, \mathcal{O}(n))$ (resp. by means of $\beta_n$: $\text{Sym}^n \Gamma(Y, \mathcal{O}(1)) \to \Gamma(Y, \mathcal{O}(n))$) is consistent.

4.B. Canonical semi-norms

Let $K$ be a local field. Let $X$ be a projective variety over $K$, $P$ a rational point in $X(K)$, and $\hat{C}$ be a smooth $K$-analytic formal curve in $\hat{X}_P$. To these data, we are going to attach a canonical semi-norm $\| \cdot \|_{X, \hat{C}}^\text{can}$ on the tangent line $T_P \hat{C}$ of $\hat{C}$ at $P$, by considering an avatar of the evaluation map $[E^i_D, E^{i+1}_D] \to \Gamma(\mathcal{P}, \mathcal{O}(D) \otimes \mathcal{N}^\vee \otimes i)$ which played a prominent role in our proof of Prop.~2.1.

The construction of $\| \cdot \|_{X, \hat{C}}^\text{can}$ will require auxiliary datas, of which it will eventually not depend.

Let us choose a line bundle $L$ on $X$ and a consistent sequence of norms on the $K$-vector spaces $E_D = \Gamma(X, L^\otimes D)$, for $D \in \mathbb{N}$. Let us also fix norms $\| \cdot \|_0$ on the $K$-lines $T_P \hat{C}$ and $L_{iP}$.

Let us denote by $C_i$ the $i$th neighborhood of $P$ in $\hat{C}$. Thus we have $C_{-1} = \emptyset$, $C_0 = \{P\}$, and $C_i$ is a $K$-scheme isomorphic to $\text{Spec} K[t]/(t^{i+1})$; moreover, $\hat{C} = \lim_{\rightarrow} C_i$. Let us denote by $E^i_D$ the $K$-vector subspace of the $s \in E_D$ such that $s|_{C_{i-1}} = 0$. The restriction map $E_D \to \Gamma(C_i, L^\otimes D)$ induces a linear map of finite dimensional $K$-vector spaces

$$\varphi^i_D: E^i_D \to \Gamma(C_i, \mathcal{O}_{C_{i-1}} \otimes L^\otimes D) \simeq (T^\vee_P \hat{C})^\otimes i \otimes L_{iP}^\otimes D.$$  

We may consider the $\| \varphi^i_D \|$ of this map, computed by using the chosen norms on $E_D$, $T_P \hat{C}$, and $L_{iP}$, and the ones they induce by restriction, duality and tensor product on $E^i_D$ and on $(T^\vee_P \hat{C})^\otimes i \otimes L_{iP}^\otimes D$.

Let us now define $\rho(L)$ by the following formula:

$$\rho(L) = \limsup_{i/\| \varphi^i_D \| \to +\infty} \frac{1}{i} \log \| \varphi^i_D \|.$$  

The analyticity of $\hat{C}$ implies that $\rho(L)$ belongs to $[-\infty, +\infty]$. As observed in [13], §3.1, when $K$ is $\mathbb{C}$ or $\mathbb{R}$, this follows from Cauchy inequality. When $K$ is ultrametric, we may actually bound $\rho(L)$ in terms of the size of $\hat{C}$:

Lemma 4.4. — Assume that $K$ is ultrametric and let $R$ be its ring of integers. Let $\mathcal{X}$ be a projective flat $R$-model of $X$ and let $\mathcal{P}: \text{Spec} R \to \mathcal{X}$ the section extending $P$. Assume moreover that the metric of $L$ is given by a line bundle $\mathcal{L}$ on $\mathcal{X}$ extending $L$ and the consistent sequence of norms on $(E_D)$ by the construction (3) in Section 4.A, and fix the norm $\| \cdot \|_0$ on $T_P \hat{C}$ so that its unit ball is equal to $N_{\mathcal{P}} \mathcal{X} \cap T_P \hat{C}$.

Then, one has

$$\rho(L) \leq -\log S_{\mathcal{X}, \mathcal{P}}(\hat{C}).$$
Proof. — Let $r$ be an element of $[0, S_X(\hat{C})]$. We claim that, with the notation above, we have:

$$\|\phi_i^D(s)\| \leq r^{-i}.$$  

This will establish that $\rho(L) = \limsup_{U \downarrow D, t \to +\infty} \frac{1}{i} \log \|\phi_i^D\| \leq -\log r$, hence the required inequality by letting $r$ go to $S_X(\hat{C})$.

To establish the above estimate on $\|\phi_i^D\|$, let us choose an affine open neighborhood $U$ of $\mathcal{P}$ in $\mathcal{X}$ such that $L_U$ admits a non-vanishing section $l$, and a closed embedding $i: U \to \mathbb{A}_R^N$ such that $i(\mathcal{P}) = (0, \ldots, 0)$. Let $\hat{C}'$ denote the image of $\hat{C}$ by $i_{KP}$. By the very definition of the size, we may find $\Phi$ in $G_{an, r}$ such that $\Phi \circ \hat{C}' = \mathbb{A}_0^l \times \{0\}^{N-1}$.

Let $s$ be an element of $\Gamma(\mathcal{X}', \mathcal{L}^{\otimes D})$. We may write $s|_U = i^* s \cdot \mathfrak{I}^{\otimes D}$ for some $\mathfrak{I}$ in $R[X_1, \ldots, X_N]$. Then, $\Phi \circ \mathfrak{I}$ is given by a formal series $g = \sum b_i X^I$ which satisfies $\|g\|_{\mathfrak{I}} \leq 1$, or equivalently, $|b_i| r|l|^i \leq 1$ for any multiindex $I$. If $s$ belongs to $E^1_D$, with the chosen normalizations of norms, we have: $\|\phi_i^D(s)\| = |b_i|_{0, \ldots, 0} \leq r^{-i}$. □

The exponential of $\rho(L)$ is a well defined element in $[0, +\infty[$, and we may introduce the following

**Definition 4.5.** — The canonical semi-norm on $T_p \hat{C}$ attached to $(X, \hat{C}, L)$ is

$$\|\cdot\|_{can, X, \hat{C}, L} := e^{\rho(L)} \cdot \|\cdot\|_0.$$  

The notation — which makes reference to $X$, $\hat{C}$, and $L$ only — is justified by the first part in the next Proposition:

**Proposition 4.6.** — a) The semi-norm $\|\cdot\|_{can, X, \hat{C}, L}$ is independent of the choices of norms on $T_p \hat{C}$ and $L|_P$, and of the consistent sequence of norms on the spaces $E_D := \Gamma(X, L^{\otimes D})$.

b) For any positive integer $k$, the semi-norm $\|\cdot\|_{can, X, \hat{C}, L}$ is unchanged if $L$ is replaced by $L^k$.

c) Let $L_1$ and $L_2$ be two line bundles and assume that $L_2 \otimes L_1^{-1}$ has a regular section $\sigma$ over $X$ that does not vanish at $P$. Then

$$\|\cdot\|_{can, X, \hat{C}, L_1} \leq \|\cdot\|_{can, X, \hat{C}, L_2}.$$  

Proof. — a) Let us denote by primes other choices of norms on the spaces $T_p \hat{C}$, $L|_P$, and $E_D$. There are positive real numbers $a, b, c$ such that $\|t\|_0 = a \|t\|_0$ for any $t \in T_p \hat{C}$, $\|s(P)\|' = b \|s(P)\|$ for any local section $s$ of $L$ at $P$, and

$$c^{-D} \|s\| \leq \|s\|' \leq c^D \|s\|$$

for any positive integer $D$ and any global section $s \in E_D$. Consequently, for $(i, D) \in \mathbb{N}^2$ and $s \in E^1_D$,

$$\|\phi_i^D(s)\|' = a^{-i} b^D \|\phi_i^D(s)\| \leq a^{-i} b^D \|\phi_i^D\| s \leq a^{-i} b^D \|\phi_i^D\| c^D \|s\|'$$

hence

$$\|\phi_i^D\|' \leq a^{-i} c^D b^D \|\phi_i^D\|.$$
and
\[ \frac{1}{i} \log \| \varphi^i_D \|' \leq -\log a + \frac{D}{i} \log (bc) + \frac{1}{i} \log \| \varphi^i_D \|. \]
When \( i/D \) goes to infinity, this implies:
\[ \rho'(L) \leq -\log a + \rho(L), \]
from which follows:
\[ (\| \cdot \|_{X,L,C}'') \leq \| \cdot \|_{X,L,C}, \]
by definition of the canonical semi-norm. The opposite inequality also holds by symmetry, hence the desired equality.

b) Denoting the line bundle as a supplementary index, one has \( \varphi^i_{D,L^k} = \varphi^i_{kD,L} \). The definition of an upper limit implies that \( \rho(L^k) \leq \rho(L) \). Conversely, let \( \rho \) be any real number such that \( \rho < \rho(L) \), and choose \( i, D, s \in E_{D,L} \) such that \( \| \varphi^i_{D,L}(s) \| \geq \rho \| s \| \).
Then,
\[ \| \varphi^i_{kD}(s^k) \| = \| \varphi^i_{D}(s) \|^k \geq \rho^k \| s \|^k, \]
so that \( \| \varphi^i_{kD} \|^1/ki \geq \rho \). Consequently, \( \rho(L^k) \geq \rho(L) \).

c) Let us use the same norm \( \| \cdot \|_0 \) on \( T_p\hat{C} \) to define \( \rho(L_1) \) and \( \rho(L_2) \). If \( s \) is a global section of \( L^1 \), then \( s \otimes \sigma^D \) is a global section of \( L^2 \), if \( s \) vanishes at order \( i \) along \( \hat{C} \), so does \( s \otimes \sigma^D \) and
\[ \varphi^i_{D,L_2}(s \otimes \sigma^D) = \sigma(P)^D \varphi^i_{D,L_1}(s). \]
Consequently,
\[ \| \varphi^i_{D,L_1}(s) \| \leq \| \varphi^i_{D,L_2} \| \| \sigma(P)^D \| s \otimes \sigma^D \| \leq \| \varphi^i_{D,L_2} \| \| s \| \]
and \( \rho(L_1) \leq \rho(L_2) \), as was to be shown.

**Corollary 4.7.** — The set of semi-norms on \( T_p\hat{C} \) described by \( \| \cdot \|_{X,L,C}^{\text{can}} \) when \( L \) varies in the class of line bundles on \( X \) possesses a maximal element, namely the canonical semi-norm \( \| \cdot \|_{X,L,C}^{\text{can}} \) attached to any ample line bundle \( L \) on \( X \).

We shall denote \( \| \cdot \|_{X,C}^{\text{can}} \) this maximal element. The formation of \( \| \cdot \|_{X,C}^{\text{can}} \) satisfies the following compatibility properties with respect to rational morphisms.

**Proposition 4.8.** — Let \( X' \) be another projective algebraic variety over \( K \), and let \( f : X \dashrightarrow X' \) be a rational map that is defined near \( P \). Let \( P' := f(P) \), and assume that \( f \) defines an (analytic, or equivalently, formal) isomorphism from \( \hat{C} \) onto a smooth \( K \)-analytic formal curve \( \hat{C}' \) in \( X'_P \).
Then for any \( v \in T_p\hat{C} \),
\[ \| Df(P) v \|_{X',f(\hat{C})} \leq \| v \|_{X,\hat{C}}. \]

If moreover \( f \) is an immersion in a neighborhood of \( P \), then the equality holds.

When \( K \) is archimedean, this summarises the results establishes in [13], sections 3.2 and 3.3. The arguments in loc. cit. may be immediately transposed to the ultrametric case, by using consistent norms as defined above instead of \( L^s \) norms on the spaces of sections \( E_D \). We leave the details to the reader.
Observe finally that this Proposition allows us to define the canonical semi-
norm \( \| \cdot \|_{X, \hat{C}}^{\text{can}} \) when the algebraic variety \( X \) over \( K \) is only supposed to be quasi-projective. Indeed, if \( \overline{X} \) denotes some projective variety containing \( X \) as an open subvariety, the semi-norm \( \| \cdot \|_{X, \hat{C}}^{\text{can}} \) is independent of the choice of \( \overline{X} \), and we let

\[
\| \cdot \|_{X, \hat{C}}^{\text{can}} := \| \cdot \|_{\overline{X}, \hat{C}}^{\text{can}}.
\]

5. Capacitary metrics on \( p \)-adic curves

5.A. Review of the complex case

Let \( M \) be a compact Riemann surface and let \( \Omega \) be an open subset of \( M \). We assume that the complementary subset to \( \Omega \) in any connected component of \( M \) is not polar. Let \( D \) be a divisor on \( M \) whose support is contained in \( \Omega \). Potential theory on Riemann surfaces (see [11], Theorem 3.1) shows the existence of a unique subharmonic function \( g_{D, \Omega} \) on \( M \) satisfying the following assumptions:

1. \( g_{D, \Omega} \) is harmonic on \( \Omega \setminus |D| \);
2. the set of points \( z \in M \setminus \Omega \) such that \( g_{D, \Omega}(z) \neq 0 \) is a polar subset of \( \partial \Omega \);
3. for any neighborhood \( V \) of \( |D| \) and any holomorphic function \( f \) on \( V \) such that \( \text{div}(f) = D \), the function \( g_{D, \Omega} - \log |f|^2 \) is harmonic on \( V \).

Moreover, \( g_{D, \Omega} \) is locally integrable on \( M \) and defines a \( L^2_1 \)-Green current for \( D \).

If \( E \) is another divisor on \( M \), one has \( g_{D+E, \Omega} = g_{D, \Omega} + g_{E, \Omega} \). Let \( \Omega_0 \) be the union of the connected components of \( \Omega \) which meet \( D \); then \( g_{D, \Omega_0} = g_{D, \Omega} \) (loc. cit., p. 258).

If \( D \) is effective, then \( g_{D, \Omega} \) takes nonnegative values (loc. cit., 3.1.4).

This function \( g_{D, \Omega} \) allows to define a metric on the line bundle \( \mathcal{O}_M(D) \), by the formula

\[
\| 1_D \|^2(z) = \exp(-g_{D, \Omega}(z)),
\]

where \( 1_D \) denotes the canonical global section of \( \mathcal{O}_M(D) \). We call this metric the capacitory metric defined by \( \Omega \) and denote by \( \| f \|_{\Omega}^{\text{cap}} \) the norm of a local section \( f \) of \( \mathcal{O}_M(D) \).

5.B. Equilibrium potential and capacity on \( p \)-adic curves

Let \( R \) be a complete discrete valuation ring and let \( K \) be its field of fractions. Let \( X \) be a smooth, projective, geometrically integral curve over \( K \) and let \( U \) be an affinoid subspace of the rigid \( K \)-analytic associated curve \( X^{an} \). We also let \( \Omega = X^{an} \setminus U \), which we view as a (non quasi-compact) rigid \( K \)-analytic curve; its affinoid subspaces are just affinoid subspaces of \( X^{an} \) disjoint of \( U \) — see Appendix B for a detailed proof that this endows \( \Omega \) with the structure of a rigid \( K \)-analytic space.

The aim of this subsection is to endow the line bundle \( \mathcal{O}(D) \), where \( D \) is a divisor which does not meet \( U \), with a canonical metric (cf. Appendix A) depending only on \( \Omega \). This parallels the similar construction for Riemann surfaces recalled in the previous subsection. Our results are very close to some of Rumely in [45]; however, our arguments come from formal geometry. An adequate potential theory on analytic curves...
in the sense of V. Berkovich, like the one developed by A. Thuillier allows a treatment which is even closer to the classical situation over the field of complex numbers (see [47], 3.6.2). In that respect, observe e.g. that in the Berkovich setting, the affinoid subspace \( U \) is a compact subset of the analytic curve attached to \( X \), and that \( \Omega \) is an open subset.

By Raynaud’s general results on formal/rigid geometry, see for instance [8, 9], there exists a normal projective flat model \( \mathcal{X} \) of \( X \) over \( R \) such that \( U \) is the set of rig points of \( X^{an} \) reducing to some open subset \( U \) of the special fibre \( X \). We shall write \( U = |U|_{\mathcal{X}} \) and say that \( U \) is the tube of \( U \) in \( \mathcal{X} \); similarly, we write \( \Omega = |\Omega| \setminus \mathcal{X} \setminus U \). (We remove the index \( \mathcal{X} \) from the notation when it is clear from the context.) The reduction map identifies the connected components of \( U \) with those of \( U \), and the connected components of \( \Omega \) with those of \( X \setminus U \). In particular, \( U \) meets any connected component of \( X \).

**Proposition 5.1.** — For any divisor \( D \) on \( X \), there is a unique \( \mathbb{Q} \)-divisor \( \mathcal{D} \) on \( \mathcal{X} \) extending \( D \) satisfying the following two properties:

1. For any irreducible component \( v \) of codimension 1 of \( X \setminus U \), \( \mathcal{D} \cdot v = 0 \).
2. The vertical components of \( \mathcal{D} \) do not meet \( U \).

Moreover, the map \( D \mapsto \mathcal{D} \) is linear and maps effective divisors to effective divisors.

**Proof.** — Let \( S \) denote the set of irreducible components of \( X \) and let \( T \subset S \) be the subset consisting of components which do not meet \( U \). Let \( D_0 \) be the schematic closure of \( D \) in \( \mathcal{X} \). Since \( U \) meets every connected component of \( X \), \( T \) does not contain all of the components of any connected component of \( X \), so that the restriction of the intersection pairing of \( \text{Div}_\mathbb{Q}(\mathcal{X}) \) to the subspace generated by the components of \( T \) is negative definite ([20], Corollaire 1.8). Therefore, there is a unique vertical divisor \( V \), linear combination of components in \( T \), such that \( (D_0 + V, s) = 0 \) for any \( s \in T \). (In the analogy with the theory of electric networks, the linear system one has to solve corresponds to that of a Dirichlet problem on a graph, with at least one electric source per connected component.) Set \( \mathcal{D} = D_0 + V \). The linearity of the map \( D \mapsto \mathcal{D} \) follows immediately from the uniqueness of \( V \).

Let us finally show that \( V \) is effective if \( D \) is. (In the graph theoretic language, this is a consequence of the maximum principle.) Denote by \( m_s \) the multiplicity of the component \( s \) in the special fibre of \( \mathcal{X} \), so that \( \sum_{s \in S} m_s s \) belongs to the kernel of the intersection pairing. Write \( V = \sum_{s \in S} c_s s \), where \( c_s = 0 \) if \( s \notin T \).

Let \( S' \) be the set of elements \( s \in S \) where \( c_s / m_s \) achieves its minimal value. Then, for any element \( \tau \) of \( S' \),

\[
0 = (c_{\tau_0} / m_{\tau_0})(\sum_{s \in S} m_s s, \tau) = c_{\tau}(\tau, \tau) + \sum_{s \neq \tau} (c_s / m_s) m_s(s, \tau) \leq c_{\tau}(\tau, \tau) + \sum_{s \neq \tau} c_s(s, \tau) = - (D_0, \tau).
\]

Since \( D_0 \) is effective and horizontal, \( (D_0, \tau) \geq 0 \), hence all previous inequalities are in fact equalities. In particular, \( (D_0, \tau) = 0 \) and \( c_s / m_s = c_{\tau} / m_{\tau} \) for any \( s \in T \) such that \( (s, \tau) \neq 0 \).
This easily implies that $S'$ contains all irreducible components $s$ which are in the same connected component of $X$ as $\tau$. By assumption, there exists at least one such $s$ which does not belong to $T$; one has therefore $c_\tau/m_\tau = c_s/m_s = 0$, hence $V$ is effective.

The following proposition explains the behaviour of these divisors $\mathcal{D}$ when the model varies.

**Proposition 5.2.** — Let $X$ and $X'$ be smooth projective curves over $K$, let $\mathcal{X}$ and $\mathcal{X}'$ be normal projective flat models over $R$ and let $\pi: \mathcal{X} \to \mathcal{X}'$ be a generically finite morphism.

Let $U$ be a Zariski open subset of the special fibre $X$ and let $U' = \pi^{-1}(U)$. Assume that $|U|_{\mathcal{X}}$ meets every connected component of $X^{an}$; then $|U'|_{\mathcal{X}'}$ meets every connected component of $(X')^{an}$.

Let $D$ and $D'$ be divisors on $X$ and $X'$ respectively, let $\mathcal{D}$ and $\mathcal{D}'$ be the extensions to $\mathcal{X}$ and $\mathcal{X}'$, relative to the open subsets $U$ and $U'$ respectively, given by Prop. 5.1.

a) Assume that $D' = \pi^* D$. If $|D|$ does not meet $|U|$, then $|D'|$ is disjoint from $|U'|$ and $\mathcal{D}' = \pi^* \mathcal{D}$.

b) Assume that $D = \pi_* D'$. If $|D'|$ does not meet $|U'|$, then $|D| \cap |U| = \emptyset$ and $\mathcal{D} = \pi_* \mathcal{D}'$.

**Proof of Prop. 5.2.** — Let $S$ denote the set of irreducible components of the special fibre $X$ of $\mathcal{X}$, the subset $T$ corresponding to the components which do not meet $U$. Define similarly $S'$ to be the set of irreducible components of $X'$, $T'$ being its subset corresponding to the components that do not meet $U'$. Let also $N$ denote the set of all irreducible components of $X'$ which are contracted to a point by $\pi$.

Mumford’s intersection theory [38] gives us a canonical section of the morphism $\pi_*: \text{Div}_Q(\mathcal{X}') \to \text{Div}_Q(\mathcal{X})$ which we shall denote by $\pi^*$, characterized by the condition that its image is orthogonal to any component in $N$. By construction, the divisor $\pi^*(\mathcal{D})$ satisfies $(\pi^*(\mathcal{D}), n) = 0$ for any $n \in N$ and has no multiplicity along the components of $N$ that are not contained in $\pi^{-1}(|\mathcal{D}|)$.

Since $U' = \pi^{-1}(U)$, $T'$ is the union of all components of $X'$ that are mapped by $\pi$, either to a point outside $U$, or to a component in $T$.

a) Let $t' \in T'$. One has $(\pi^* \mathcal{D}, t') = (\mathcal{D}, \pi_*(t')) = 0$ since $t'$ maps to a component in $T$, or to a point. Moreover, by the construction of $\pi^*$, the vertical components of $\pi^* \mathcal{D}$ are elements $s' \in S'$ such $\pi(s')$ meets the support of $\mathcal{D}$. By assumption, the Zariski closure of $D$ in $X$ is disjoint from $U$; in other words, the vertical components of $\pi^* \mathcal{D}$ all belong to $T'$. This shows that the divisor $\pi^* \mathcal{D}$ on $\mathcal{X}'$ satisfies the conditions of Prop. 5.1; since it extends $D' = \pi^* D$, one has $\pi^* \mathcal{D} = \mathcal{D}'$.

b) Let $s$ be a vertical component appearing in $\pi_*(\mathcal{D}')$; necessarily, there is a vertical component $s'$ of $\mathcal{D}'$ such that $s = \pi(s')$. This implies that $s' \in T'$, hence $s \in T$. For any $t \in T$, $\pi^*(t)$ is a linear combination of vertical components of $X'$ contained in $\pi^{-1}(t)$. Consequently, they all belong to $T'$ and one has $(\pi_*(\mathcal{D}'), t) = (\mathcal{D}', \pi^*(t)) = 0$. By uniqueness, $\pi_*(\mathcal{D}) = \mathcal{E}$. 

\qed
Corollary 5.3. — Let $X$ be a projective smooth algebraic curve over $K$, let $U$ be an affinoid subspace of $X$ which meets any connected component of $X$. Let $D$ be a divisor on $X$ whose support is disjoint from $U$.

Then the metrics on the line bundle $\mathcal{O}_X(D)$ induced by the line bundle $\mathcal{O}_X(D)$ defined by Prop 5.1 does not depend on the choice of the projective flat model $\mathcal{X}'$ of $X$ such that $U$ is the tube of a Zariski open subset of the special fibre of $\mathcal{X}$.

Proof. — For $i = 1, 2$, let $(\mathcal{X}_i, U_i)$ be a pair as above, consisting of a normal flat, projective model $\mathcal{X}_i$ of $X$ over $R$ and an open subset $U_i$ of its special fibre $X_i$ such that $|U_i|_{\mathcal{X}_i} = U$. Let $D_i$ denote the extension of $D$ on $\mathcal{X}_i$ relative to $U_i$.

There exists a third model $(\mathcal{X}', U')$ which admits maps $\pi_i: \mathcal{X}' \to \mathcal{X}_i$, for $i = 1, 2$, extending the identity on the generic fibre. Let $D'$ denote the extension of $D$ on $\mathcal{X}'$. For $i = 1, 2$, one has $\pi_i^*(U_i) = U'$. By Prop. 5.2, one thus has the equalities $\pi'^*D_i = D'$ hence the line bundles $\mathcal{O}_{\mathcal{X}'}(D')$ on $\mathcal{X}'$ and $\mathcal{O}_{\mathcal{X}_i}(D_i)$ on $\mathcal{X}$ induce the same metric on $\mathcal{O}_X(D)$.

We shall call this metric the capacitary metric and denote as $\|f\|_{\mathcal{O}_X(D)}^\cap$ the norm of a local section $f$ of $\mathcal{O}_X(D)$ for this metric.

Proposition 5.4. — Let $X$ be a projective smooth algebraic curve over $K$, let $U$ be an affinoid subspace of $X$ which meets any connected component of $X$. Let $D$ be a divisor on $X$ whose support is disjoint from $U$ and let $\Omega = X^{\text{an}} \setminus U$.

If $\Omega'$ denotes the union of the connected components of $\Omega$ which meet $|D|$, then the capacitary metrics of $\mathcal{O}(D)$ relative to $\Omega$ and to $\Omega'$ coincide.

Proof. — Let us fix a normal projective flat model $\mathcal{X}$ of $X$ over $R$ and a Zariski open subset $U$ of its special fibre $X$ such that $U = |U|_{\mathcal{X}}$. Let $Z = X \setminus U$ and let $Z'$ denote the union of those connected components of $Z$ which meet the specialization of $|D|$. Then $\Omega' = |Z'|$ is the complementary subset to the affinoid $|U'|$, where $U' = X \setminus Z'$; in particular, $|U'|$ meets every connected component of $X^{\text{an}}$.

Let $D_0$ denote the horizontal divisor on $\mathcal{X}$ which extends $D$. The divisor $D' := D_{\Omega'}$ is the unique $\mathbb{Q}$-divisor of the form $D_0 + V$ on $\mathcal{X}$ where $V$ is a vertical divisor supported by $Z'$ such that $(D', t) = 0$ for any irreducible component of $Z'$. By the definition of $Z'$, an irreducible component of $Z$ which is not contained in $Z'$ doesn't meet neither $Z'$, nor $D_0$. It follows that for any such component $t$, $(D', t) = (D_0, t) + (V, t) = 0$. By uniqueness, $D'$ is the extension of $D$ on $\mathcal{X}$ relative to $U$, so that $D_{\Omega'} = D_{\Omega}$. This implies the proposition.

As an application of the capacitary metric, we refine in the next proposition a classical theorem by Fresnel and Matignon ([24], théorème 1) according to which affinoids of a curve can be defined by one equation. While these authors make no hypothesis concerning the residue field of $k$, or the complementary subset of the affinoid $U$, we are able to impose the polar divisor of $f$. Using the terminology of Rumely ([45], §4.2, p. 220), this proposition signifies that affinoid subsets of a curve are RL-domains.
The proofs in both references are similar and rely on the Abel-Jacobi map, together with the fact that $K$ is the union of its locally compact subfields.
Let $t \in T$. One has $(\text{div}(f_s), t) = 0$, hence
\[(W_s, t) = n_s(\emptyset, t) - (E_s, t) = 0.\]
Similarly, if $s' \in S \setminus T$, $(\text{div}(f_{s'}), s') = 0$ and
\[(W_s, s') = n_s(\emptyset, s') - (E_s, s')
= n_s(\emptyset, 0) + n_s(V, s') - (E_s, s')
= 0 + n_s a_{s'} - (E_s, s').\]
If $s' \neq s$, it follows that
\[(W_s, s') = n_s a_{s'},\]
while
\[(W_s, s) = n_s a_s - \frac{n_s}{m_s} \deg(D).\]

We now define a vertical divisor
\[W = \sum_{s \not\in T} \frac{a_s m_s}{n_s} W_s.\]
For any $t \in T$, $(W, t) = 0$. Moreover, for any $s' \in S \setminus T$,
\[(W, s') = \sum_{s \not\in T} \frac{a_s m_s}{n_s} (W_s, s')
= \sum_{s \not\in T} a_s m_s a_{s'} - \frac{a_{s'}}{n_{s'}} n_{s'} \deg(D)
= a_{s'} \left( \sum_{s \not\in T} a_s m_s \right) - a_{s'} \deg(D),\]
hence $(W, s') = 0$ by Eq. (5.6). Therefore, the vertical $\mathbb{Q}$-divisor $W$ is a multiple of the special fibre and there is $\lambda \in \mathbb{Q}$ such that $W = \lambda F$. Finally,
\[\sum_{s \not\in T} \frac{a_s m_s}{n_s} \text{div}(f_s) - \lambda F = -\deg(D)\emptyset + \sum_{s \not\in T} \frac{a_s m_s}{n_s} E_s\]
is a principal $\mathbb{Q}$-divisor. It follows that there are positive integers $\mu$ and $\lambda_s$, for $s \not\in T$, such that
\[\mathcal{D} = \sum_{s \not\in T} \lambda_s E_s - \mu \emptyset\]
is the divisor of a rational function $f \in K(X)$.

By construction, the polar divisor of $f$ on $X$ is a multiple of $D$. Moreover, the reduction of any $x \not\in U$ belongs to a component labelled by $T$ at which the multiplicity of $\mathcal{D}$ is positive. Consequently, $|f(x)| > 1$. On the contrary, if $x \in U$, it reduces to a component outside $T$ and $|f(x)| \leq 1$. More precisely, $|f(x)| < 1$ if and only if $x$ reduces to one of the points $x_s$, $s \not\in T$.

The definition of an algebraic metric now implies the following explicit description of the capacitary metric.
Corollary 5.7. — Let \((X, U)\) be as above; denote \(\Omega = X^\text{an} \setminus U\). Let \(D\) be any divisor which does not meet \(U\), and let \(f\) be a rational function defining \(U\), as in preceding proposition, and whose polar divisor is equal to \(mD\), for some positive integer \(m\). Then, the capacitary metric on \(\mathcal{O}_X(D)\) can be computed as

\[-\log \|1_D\|^\text{cap}_\Omega(x) = \frac{1}{m} \log^+ |f(x)| = \max(0, \log|f(x)|^{1/m}).\]

Proposition 5.8. — Let \((X, U)\) and \((X', U')\) be as above, denote \(\Omega' = (X')^\text{an} \setminus U'\) and \(\Omega = X^\text{an} \setminus U\) and let \(\varphi : \Omega' \to \Omega\) be any rigid analytic isomorphism. Let \(D'\) be any divisor in \(X'\) whose support does not meet \(U'\) and let \(D = \varphi(D')\).

Then, for any \(x \in \Omega'\),

\[\|1_{D'}\|^\text{cap}_\Omega(x) = \|1_D\|^\text{cap}_\Omega(\varphi(x)).\]

Proof. — By linearity, we may assume that \(D\) is effective. Let \(f \in K(X)\) and \(f' \in K(X')\) be rational functions as in Proposition 5.5. Let \(m\) and \(m'\) be positive integers such that the polar divisor of \(f\) and \(f'\) are \(mD\) and \(m'D\) respectively. The function \(f \circ \varphi\) is a meromorphic function on \(\Omega'\) whose divisor is \(mD'\). Consequently, the meromorphic function on \(\Omega'\)

\[g = (f \circ \varphi)^{m'} / (f')^m\]

is in fact invertible. We have to prove that \(g|\Omega'(x) = 1\) for any \(x \in \Omega'\).

Let \((\varepsilon_n)\) be any decreasing sequence of elements of \(\sqrt{|K^*|}\) converging to 1. The sets \(V'_n = \{x \in X' ; |f'(x)| \geq \varepsilon_n\}\) are affinoid subspaces of \(\Omega'\) and exhaust it. By the maximum principle (see Prop. B.1 below), one has

\[\sup_{x \in V'_n} |g(x)| = \sup_{|f'(x)|=\varepsilon_n} |g(x)| \leq 1 / (\varepsilon_n)^m \leq 1.\]

Consequently, \(\sup_{x \in \Omega'} |g(x)| \leq 1\). The opposite inequality is shown similarly by considering the isomorphism \(\varphi^{-1} : \Omega \to \Omega'\). This proves the proposition. \(\square\)

5.C. Capacitary norms on tangent spaces

Definition 5.9. — Let \((X, U, \Omega)\) be as above and let \(P \in \Omega\). Let us endow the line bundle \(\mathcal{O}_X(P)\) with its capacitary metric relative to \(\Omega\). The capacitary norm \(\|\cdot\|^\text{cap}_P\) on the \(K\)-line \(T_P X\) is then defined as the restriction of \((\mathcal{O}_X(P), \|\cdot\|)\) to the point \(P\), composed by the adjunction formula \(\mathcal{O}_X(\mathcal{O}_X(P)|_P) \cong T_P X\).

Example 5.10. — Let \(\Omega\) be the set of rig-points of \(X^\text{an}\) which have the same reduction \(P\) as \(P\). In other words, \(U\) is the affinoid in \(X^\text{an}\), inverse image of the open subset \(U\) defined as the complement of \(P\). Then, \(\Omega\) is isomorphic to the open unit ball, the divisor \(\mathcal{P}\) is simply the image of the section which extend the point \(P\), and the capacitary metric on \(T_P S\) is simply the metric induced by the integral model.

Example 5.11 (Comparison with other definitions). — Let us show that how this norm fits with Rumely’s definition in [45] of the capacity of \(U\) with respect to the point \(P\). Let \(f\) be a rational function on \(X\), without pole except \(P\), such that \(U = \{x \in X ; |f(x)| \leq 1\}\). Let \(m\) be the order of \(f\) at \(P\) and let us define \(c_P \in K^*\) so that
\( f(x) = c_p t(x)^{-m} + \ldots \) around \( P \), where \( t \) is a fixed local parameter at \( P \). By definition of the adjunction map, the local section \( \frac{1}{t} \rho \) of \( \mathcal{O}_X(P) \) maps to \( \frac{\partial}{\partial t} \). Consequently,

\[
(5.12) \quad \| \frac{\partial}{\partial t} \|_{\mathcal{O}^\cap \Omega} = \| \frac{1}{t} \rho \|_P = \lim_{x \to P} |t(x)|^{-1} \min(1, |f(x)|^{-1/m}) = |c_p|^{-1/m}.
\]

As an example, and to make explicit the relation of our rationality criterion below with the classical theorem of Borel-Dwork, let us consider the classical case in which \( X = \mathbf{P}^1 \) (containing the affine line with \( t \) coordinate), and \( U \) is the affinoid subspace of \( \mathbf{P}^1 \) defined by the inequality \( |t| \geq r \) (to which we add the point at infinity, where \( r \in \sqrt{|K^*|} \)). Let us note \( \Omega = \mathcal{C} \mathcal{U} \) and choose for the point \( P \in \Omega \) the point with coordinate \( t = 0 \). Let \( m \) be a positive integer and \( a \in K^* \) such that \( r^m = |a| \); let \( f = a/t^m \); this is a rational function on \( \mathbf{P}^1 \) with a single pole at \( P \) and \( U \) is defined by the inequality \( |f| \leq 1 \). It follows that

\[
\| \frac{\partial}{\partial t} \|_{\mathcal{O}^\cap \Omega} = |a|^{-1/m} = 1/r.
\]

Similarly, assume that \( U \) is an affinoid subset of \( \mathbf{P}^1 \) which does not contain the point \( P = \infty \). Then \( U \) is bounded and \( \| t^2 \frac{\partial}{\partial t} \|_{\mathcal{O}^\cap \Omega} \) is nothing but its transfinite diameter in the sense of Fekete. (See [1], the equivalence of both notions follows from [45], theorem 4.1.19, p. 204; see also loc. cit., theorem 3.1.18, p. 151 for its archimedean counterpart.)

**Remarks 5.13.** — a) Let \( (X, U) \) be as above, let \( P \in X(K) \) be a rational point such that \( P \notin U \). Let \( \Omega = X^{an} \setminus U \) and define \( \Omega_0 \) to be the connected component of \( \Omega \) which contains \( P \). It follows from Prop. 5.4 that the norms \( \| \cdot \|_{\mathcal{O}^\cap \Omega_0} \) and \( \| \cdot \|_{\mathcal{O}^\cap \Omega} \) on \( T_P X \) coincide.

b) Let \( U' \) be another affinoid subspace of \( X^{an} \) such that \( U' \subset U \); the complementary subset \( \Omega' \) to \( U' \) satisfies \( \Omega \subset \Omega' \). If moreover \( \Omega \) and \( \Omega' \) are connected, then for any \( P \in \Omega \) and any vector \( v \in T_P X \), one has

\[
\| v \|_{\mathcal{O}^\cap \Omega} \leq \| v \|_{\mathcal{O}^\cap \Omega'}.
\]

Indeed, since \( \Omega \) and \( \Omega' \) are connected and contain \( P \), Prop. 5.5 implies that there exist rational functions \( f \) and \( f' \) on \( X \), without pole except \( P \), such that the affinoids \( U \) and \( U' \) are defined by the inequalities \( |f| \leq 1 \) and \( |f'| \leq 1 \) respectively. Replacing \( f \) and \( f' \) by some positive powers, we may also assume that \( \text{ord}_P(f) = \text{ord}_P(f') \); let us denote it by \( -d \). Let \( t \) be a local parameter at \( P \); it is enough to prove the desired inequality for \( v = \frac{\partial}{\partial t} \).

We may expand \( f \) and \( f' \) around \( P \) as Laurent series in \( t - t(P) \), writing

\[
f = \frac{c}{(t - t(P))^d} + \ldots, \quad f' = \frac{c'}{(t - t(P))^d} + \ldots.
\]

The rational function \( g = f/f' \) on \( X \) defines a holomorphic function on the affinoid subspace defined by the inequality \( |f'| \geq 1 \), since the poles at \( P \) at the numerator and at the denominator cancel each other; moreover, \( g(P) = c/c' \). Using twice the maximum principle (Prop. B.1), we have

\[
|g(P)| \leq \sup_{|f'(x)| \geq 1} |g(x)| = \sup_{|f'(x)| = 1} |g(x)| = \sup_{|f'(x)| = 1} 1 \leq 1
\]

and

\[
|f(x)| \leq 1.
\]
since $\Omega \subset \Omega'$. This implies that $|g(P)| \leq 1$, so that $|c| \leq |c'|$. Therefore,

$$\frac{\partial}{\partial t} \|_P^\text{cap} = |c'|^{-1/d} \leq |c|^{-1/d} = \frac{\partial}{\partial t} |c|^{\text{cap}}_P,$$

as was to be shown.

5.D. Canonical semi-norms and capacities

Let $K$ be a local field. In the case $K$ is archimedean, we assume moreover that $K = \mathbb{C}$; let $M$ be a connected Riemann surface, $\Omega$ be an open subset in $M$, relatively compact.

In the case $K$ is ultrametric, let $M$ be a smooth projective curve over $K$, let $U$ be an affinoid in $X$, let us denote $\Omega = X \setminus U$. In both cases, let $O$ be a point in $\Omega$.

We endow the $K$-line $T_O M$ with its capicity semi-norm, as defined by the first author in [13] when $K = \mathbb{C}$, or by the previous section in the $p$-adic case.

Let $X$ be a projective variety over $K$, let $P \in X(K)$ be a rational point and let $\mathring{C}$ be a smooth formal curve in $\mathring{X}_P$. Let $\varphi : \Omega \to X^\text{an}$ be an analytic map such that $\varphi(O) = P$ which maps the germ of $\Omega$ at $O$ to $\mathring{C}$. (Consequently, if $\varphi(O) \neq 0$, then $\varphi$ defines an analytic isomorphism from the formal germ of $\Omega$ at $O$ to $\mathring{C}$.) We endow $T_P X$ with its canonical semi-norm $\| \cdot \|_{X, \mathring{C}, P}^\text{cap}$.

**Proposition 5.14.** — For any $v \in T_O \Omega$, one has

$$\|D\varphi(O)(v)\|_{X, \mathring{C}, P}^\text{cap} \leq \|v\|_{\Omega, P}^\text{cap}.$$

**Proof.** — The case $K = \mathbb{C}$ is treated in [13], Prop. 3.6. It therefore remains to treat the ultrametric case.

In view of remark 5.13, a), we may assume that $\Omega$ is connected. By Prop. 5.5, there exists a rational function $f \in K(M)$ without pole except $O$ such that $U = \{ x \in M ; |f(x)| \leq 1 \}$. Let $m > 0$ denote the order of the pole of $f$ at the point $O$. For any real number $r > 1$ belonging to $\sqrt{|K|}$, let us denote by $U_r$ and $\partial U_r$ the affinoids $\{|f(x)| \geq r\}$ and $\{|f(x)| = r\}$ in $M$. One has $\bigcup_{r > 1} U_r = \Omega$. We shall denote by $\varphi_r$ the restriction of $\varphi$ to the affinoid $U_r$. Let us also fix a local parameter $t$ at $O$ and let us define $c_p = \lim_{x \to O} t(x)^m f(x)$.

One has $\|x\|_{O, \Omega}^\text{cap} = |c_p|^{-1/m}$.

Let $L$ be an ample line bundle on $X$. For the proof of the proposition, we may assume that $D\varphi(O)$ is non zero; then $\varphi_r$ is a formal isomorphism and we may consider the formal parameter $\tau = t \circ \varphi_r^{-1}$ on $\mathring{C}$ at $P$. We have $dt = \varphi^* d\tau$, hence $D\varphi(O)\left(\frac{\partial}{\partial \tau}\right) = \frac{\partial}{\partial t}$. Let us also fix a norm $\| \cdot \|_0$ on the $K$-line $T_P \mathring{C}$, and let us still denote by $\| \cdot \|_0$ the associated norm on its dual $T_P^* \mathring{C}$.

Let us choose a real number $r > 1$ such that $r \in \sqrt{|K|}$, fixed or the moment. Since the residue field of $K$ is finite, the line bundle $\varphi_r^* L$ on $U_r$ is torsion (see [40], Prop. 3.1); we may therefore consider a positive integer $n$ and a nonvanishing section $\varepsilon$ of $\varphi_r^* L^\otimes n$. For any integer $D$ and any section $s \in \Gamma(X, L^\otimes nD)$, let us write $\varphi_r^* s = \sigma \varepsilon^{\otimes nD}$, where $\sigma$ is an analytic function on $U_r$. Since we assumed that $D\varphi(O) \neq 0$, the condition that $s$ vanishes at order $i$ along $\mathring{C}$ means exactly that $\sigma$ vanishes at order $i$ at $O$. Consequently,
the $i$-th jet of $\varphi_s^*$ at $O$ is given by

$$j^i_O(s) = (\sigma t^{-i})(O)\epsilon^{nD}(O) \otimes d\tau^{s_i}. $$

Writing $(\sigma t^{-i}) = (\sigma f^i)(t^m)^{-i}$, it follows that

$$\|j^i_O(s)\| = |\sigma f^i| |O| |c_p|^{-i} \|\epsilon(O)\|^{nD} \|d\tau\|^{i}. $$

Notice that $\sigma f^i$ is an analytic function on $U_r$. By the maximum principle (Prop. B.1),

$$|\sigma f^i| (O) \leq \sup_{U_r} |\sigma f^i| = \sup_{x \in \partial U_r} |\sigma f^i(x)| = \|\sigma f^i\|_{\partial U_r}. $$

Consequently,

$$\|j^i_O(s)\| \leq \|\sigma f^i\|_{\partial U_r} |c_p|^{-i} |f^i| |\epsilon(O)\|^{nD} \|d\tau\|^{i}.$$

With the notations of Section 4.B, it follows that the norm of the evaluation morphism

$$\varphi^{i}_{nD}: E^{i}_{nD} \rightarrow L^{\otimes nD}_{P} \otimes (T^{\hat{V}}_{P} \hat{C})^{\otimes i}$$

satisfies the inequality

$$\|\varphi^{i}_{nD}\|^{1/i} \leq r^{1/m} |c_p|^{-1/m} |\epsilon(O)\|^{0} \|\epsilon\|^{nD/i} \|d\tau\|^{0}. $$

This implies that

$$\rho(L) = \rho(L^{\otimes n}) = \limsup_{i \rightarrow D} \frac{1}{i} \log \|\varphi^{i}_{nD}\| \leq \frac{1}{m} \log \frac{r}{|c_p|} = \log \|d\tau\|^{0}. $$

By the definition of the canonical semi-norm, we thus have

$$\|D\varphi(O) (\frac{\partial}{\partial t})_{X,C,P}^{\text{can}}\| = \|\frac{\partial}{\partial t}\|_{X,C,P}^{\text{can}} = \rho(L) \|\frac{\partial}{\partial t}\|^{0} \leq \left( \frac{r}{|c_p|} \right)^{1/m} = r^{1/m} \|\frac{\partial}{\partial t}\|_{\Omega,C,P}^{\text{cap}}. $$

Letting $r$ go to 1, we obtain the desired inequality. \qed

5.E. Global capacities

Let $K$ be a number field, let $R$ denote the ring of integers in $K$. Let $X$ be a projective smooth algebraic curve over $K$.

Our goal in this Section is to show how capacitary metrics at all places fit within the framework of the Arakelov intersection theory (with $L^2$-regularity) introduced in [11]. Let us briefly recall here the main notations and properties of this arithmetic intersection theory, referring to this article for more details.

For any projective flat model $\mathcal{X}$ of $X$ over $R$, the Arakelov Chow group $\text{CH}^1_R(\mathcal{X})$ consists of equivalence classes of pairs $(\mathcal{D}, g) \in \mathcal{Z}_1^R(\mathcal{X})$ where $\mathcal{D}$ is a $R$-divisor on $\mathcal{X}$ and $g$ is a Green current with $L^2$-regularity on $\mathcal{X}(C)$ for the real divisor $\mathcal{D}_X$, stable under complex conjugation. Arithmetic intersection theory endows it with a symmetric $R$-valued bilinear form. Moreover, any class $\alpha \in \text{CH}^1_R(\mathcal{X})$ defines a height $h_\alpha$ which is
a linear function on the vector space $\mathbb{Z}_R^1(\mathcal{X})$ of real 1-cycle on $\mathcal{X}$. If $D$ is a real divisor on $X$, we shall still denote $h_\alpha(D)$ the height of the unique horizontal 1-cycle on $\mathcal{X}$ which extends $D$.

Any morphism $\pi: \mathcal{X}' \to \mathcal{X}$ between projective flat models of curves $X'$ and $X$ induces morphisms of abelian groups $\pi_*: \widehat{\text{CH}}_R^1(\mathcal{X}') \to \widehat{\text{CH}}_R^1(\mathcal{X})$ and $\pi^*: \widehat{\text{CH}}_R^1(\mathcal{X}) \to \widehat{\text{CH}}_R^1(\mathcal{X}')$. For any classes $\alpha$ and $\beta \in \widehat{\text{CH}}_R^1(\mathcal{X})$, $\gamma \in \widehat{\text{CH}}_R^1(\mathcal{X}')$, one has $\pi^* \alpha \cdot \pi^* \beta = \alpha \cdot \beta$ and a projection formula $\pi_*(\pi^* \alpha \cdot \gamma) = \deg(\pi) \alpha \cdot \pi_*(\gamma)$, when $\pi$ has constant generic degree $\deg(\pi)$. Moreover, for any divisor $D$ on $X$, there is the equality $h_{\pi^* \alpha}(D) = \deg(\pi)(\pi_*(\alpha))$. For any ultrametric place $v$ of $X$, let us denote by $K_v$ the completion of $v$ and by $X_v$ the rigid $K_v$-analytic variety attached to $X_{K_v}$. For any archimedean place $v$ of $X$, corresponding to an embedding $\sigma: K \to \mathbb{C}$, we let $X_v$ be the compact Riemann surface $X_\sigma(\mathbb{C})$.

**Definition 5.15.** — Let $D$ be an effective reduced divisor on $X$. For each place $v$ of $K$, let $\Omega_v$ be an open subset of $X_v$. One says that the collection $(\Omega_v)$ is an adelic tube adapted to $D$ if the following conditions are satisfied:

1. for any ultrametric place $v$, the complement of $\Omega_v$ in any connected component of $X_v$ is a non-empty affinoid subset;
2. for any archimedean place $v$, the complement of $\Omega_v$ in any connected component of $X_v$ is non-polar;
3. there exists a divisor $E$ whose support contains $|D|$, a finite set of places $F$ of $K$, a projective flat model $\mathcal{X}$ of $X$ over $R$ of integers such that for any ultrametric place $v$ of $K$ such that $v \notin F$, $\Omega_v = |\mathcal{X}|_v$ is the tube in $X_v$ around the specialization of $E$ in the special fibre $\mathcal{X}_{F_v}$.

Let $\Omega = (\Omega_v)$ be a family, where, for each place $v$ of $K$, $\Omega_v$ is an open subset of the analytic curve $X_v$ satisfying the conditions (1) and (2). Let $D$ be a divisor on $X$ whose support is contained in $\Omega_v$ for any place $v$ of $K$. By the considerations of this section, the line bundle $\mathcal{O}_X(D)$ is then endowed, for each place $v$ of $K$, of a $v$-adic metric $\|\cdot\|^{\text{cap}}_{\Omega_v}$. If $\Omega$ is an adelic tube adapted to $D$, then, for almost all places of $K$, this metric is in fact induced by the horizontal extension of the divisor $D$ in an adequate model $\mathcal{X}$ of $X$. Actually, one has the following proposition:

**Proposition 5.16.** — Assume that $\Omega$ is an adelic tube adapted $|D|$. There is a normal, flat, projective model $\mathcal{X}$ of $X$ over $R$ and a (unique) Arakelov $\mathbb{Q}$-divisor extending $D$, inducing at any place $v$ of $K$ the $v$-adic capacitary metric on $\mathcal{O}_X(D)$. Such an arithmetic surface $\mathcal{X}$ will be said adapted to $\Omega$. Then, the Arakelov $\mathbb{Q}$-divisor on $\mathcal{X}$ whose existence is asserted by the proposition will be denoted $\hat{D}_{\Omega}$.

**Proof.** — It has already been recalled that archimedean Green functions defined by potential theory have the required $L^1$-regularity. It thus remains to show that the metrics at finite places can be defined using a single model $(\mathcal{X}, D)$ over $R$. 
Let $\mathcal{X}_0$ be a model of $X$ over $R$ and $F$ be a finite set of places satisfying the conditions introduced in the definition of an adelic tube.

**Lemma 5.17.** — There exists a normal, flat projective model $\mathcal{X}$ of $X$ over $R$, and, for any ultrametric place $v$ of $K$, a Zariski closed subset $Z_v$ of the special fibre $\mathcal{X}_{F_v}$ at $v$ such that $\Omega_v = |Z_v|$.

**Proof.** — Let $R_0$ be the subring of $K$ obtained from $R$ by localizing outside places in $F$. The normalization $\mathcal{X}_0$ of $\mathcal{X}_1$ is finite over $\mathcal{X}_1$ ($\mathcal{Z}$ is excellent), hence projective. (In fact, by resolution of singularities of 2-dimensional excellent schemes, we may even assume that $\mathcal{X}_0$ is regular.) Up to enlarging $F$, we may also assume that the natural map $\mathcal{X}_0 \to \mathcal{X}_1$ is an isomorphism over $R_0$.

By Raynaud’s formal/rigid geometry comparison theorem, there is, for each finite place $v \in F$, a normal projective and flat model $\mathcal{X}_v$ of $X$ over the completion $\hat{R}_v$, a Zariski closed subset $Z_v$ the special fibre of $\mathcal{X}_v$, such that $\Omega_v = |Z_v|$.

By a general descent theorem of Moret-Bailly ([37], th. 1.1; see also [10], 6.2, lemma D), there exists a projective and flat $R$-scheme $\mathcal{X}$ which coincides with $\mathcal{X}_0$ over $\text{Spec} R_0$ and such that its completion at any finite place $v \in F$ is isomorphic to $\mathcal{X}_v$.

For any ultrametric place $v$ over $\text{Spec} R_0$, we just let $Z_v$ be the specialization of $D$ in $\mathcal{X}_{F_v} = (\mathcal{X}_0)_{F_v}$; one has $\Omega_v = |Z_v|$ by assumption since $v \not\in F$. For any ultrametric place $v \in F$, $Z_v$ identifies with a Zariski closed subset of the special fibre $\mathcal{X}_{F_v}$ and its tube is equal to $\Omega_v$ by construction. This concludes the proof of the lemma.

Fix such a model $\mathcal{X}$ and let $\mathcal{D}_0$ be the Zariski closure of $D$ in $\mathcal{X}$. For any ultrametric place $v$ of $F$, let $V_v$ be the unique divisor on the special fibre $\mathcal{X}_{F_v}$ such that $\mathcal{D}_0 + V_v$ satisfies the assumptions of Prop. 5.1. One has $V_v = 0$ for any ultrametric place $v$ such that $Z_v$ has no component of dimension 1, hence for all but finitely places $v$. We thus may consider the $\mathbb{Q}$-divisor $\mathcal{D} = \mathcal{D}_0 + \sum_v V_v$ on $\mathcal{X}$ and observe that it induces the capacitary metric at all ultrametric places.

**Proposition 5.18.** — Let $D$ be a divisor on $X$ and let $\Omega$ be an adelic tube adapted to $|D|$. One has the equality

$$\widehat{D}_\Omega \cdot \widehat{D}_\Omega = h_{\widehat{D}_\Omega}(D).$$

**Proof.** — Let us consider a model $\mathcal{X}$ of $X$ and an Arakelov $\mathbb{Q}$-divisor $\mathcal{D}$ on $\mathcal{X}$ defining the capacitary metric $\|\cdot\|_\cap$ at all ultrametric places $v$ of $K$.

Let $\mathcal{D}_0$ denote the Zariski closure of $D$ in $\mathcal{X}$. For any ultrametric place $v$ of $K$, and let $V_v$ be the vertical part of $\mathcal{D}$ lying above $v$ so that $\mathcal{D} = \mathcal{D}_0 + \sum_v V_v$.

By the definition of the capacitary metric at ultrametric places, the geometric intersection number of $\mathcal{D}$ with any vertical component of $\mathcal{D}$ is zero. Consequently,

$$\widehat{D}_\Omega \cdot \widehat{D}_\Omega = h_{\widehat{D}_\Omega}(\mathcal{D}_0) + \sum_v h_{\widehat{D}_\Omega}(V_v) = h_{\widehat{D}_\Omega}(\mathcal{D}_0),$$

as was to be shown.
Corollary 5.19. — Let \( P \in X(K) \) be a rational point of \( X \) and let \( \Omega \) be an adelic tube adapted to \( P \). One has

\[ \hat{P}_\Omega \cdot \hat{P}_\Omega = \overline{\deg}(T_P X, \| \cdot \|_\Omega^{cap}). \]

6. An algebraicity criterion for \( A \)-analytic curves

Let \( K \) be a number field, \( R \) its ring of integers, \( X \) a quasi-projective algebraic variety over \( K \) and let \( P \) a point in \( X(K) \). Let \( \hat{C} \hookrightarrow \hat{X}_P \) be a smooth formal curve that is \( A \)-analytic.

For any place \( v \) of \( K \), the formal curve \( \hat{C} \) is \( K_v \)-analytic, and we may equip the \( K \)-line \( T_P \hat{C} \) with the canonical \( v \)-adic semi-norm \( \| \cdot \|_v^{can} = \| \cdot \|_{X, \hat{C}, P_v}^{can} \) constructed in Section 4.B.

We claim that, equipped with these semi-norms, \( T_P \hat{C} \) defines a semi-normed \( K \)-line \( (T_P \hat{C}, \| \cdot \|^{can}) \) with a well-defined Arakelov degree in \( ]-\infty, +\infty[ \), in the sense of [13], 4.2. Recall that it means that, for any (or equivalently, for some) non-zero element in \( T_P \hat{C} \), the series \( \sum_v \log^+ \| t \|_v^{can} \) is convergent. To see this, consider a quasi-projective flat \( R \)-scheme \( \mathcal{X} \) with generic fibre \( X \) together with a section \( \mathcal{P} : \text{Spec} R \to \mathcal{X} \) which extends \( P \). According to Lemma 4.4 (applied to projective compactifications of \( X \) and \( \mathcal{X} \), and an ample line bundle \( \mathcal{L} \)), the inequality

\[ \log \| t \|_v^{can} \leq -\log S_{\mathcal{X}, v}(\hat{C}), \]

holds for almost all finite places \( v \), where \( S_{\mathcal{X}, v} \) denotes the size of \( \hat{C} \) with respect to the \( R_v \) model \( \mathcal{X} \otimes R_v \). Since by definition of \( A \)-analyticity the series with non-negative terms \( \sum_v \log S_{\mathcal{X}, v}(\hat{C})^{-1} \) has a finite sum, this establishes the required convergence.

The Arakelov degree of \( (T_P \hat{C}, \| \cdot \|^{can}) \) is defined as the sum:

\[ \overline{\deg}(T_P \hat{C}, \| \cdot \|^{can}) := \sum_v (\log \| t \|_v^{can}). \]

It is a well defined element in \( ]-\infty, +\infty[ \), independent of the choice of \( t \) by the product formula (we follow the usual convention \( -\log 0 = +\infty \)).

The following criterion extends Theorem 4.2 of [13], where instead of canonical semi-norms, larger norms constructed by means of the sizes were used at finite places.

Theorem 6.1. — Let \( \hat{C} \) be, as above, an \( A \)-analytic curve through a rational point \( P \) in some algebraic variety \( X \) over \( K \).

If \( \overline{\deg}(T_P \hat{C}, \| \cdot \|^{can}) > 0 \), then \( \hat{C} \) is algebraic.

Proof. — We keep the above notation, and we assume, as we may, \( X \) (resp. \( \mathcal{X} \)) to be projective over \( K \) (resp. over \( R \)). We choose an ample line bundle \( \mathcal{L} \) over \( \mathcal{X} \) and we let \( L := \mathcal{L}_K \).

We let \( \mathcal{E}_D := \Gamma(\mathcal{X}, \mathcal{L}^\otimes D) \) and, for any embedding \( \sigma : K \hookrightarrow \mathbb{C} \), we choose a consistent sequence of hermitian norms \( (\| \cdot \|_{D, \sigma}) \) on the \( \mathbb{C} \)-vector spaces \( \mathcal{E}_{D, \sigma} = \Gamma(X, L^\sigma D) \), in a way compatible with complex conjugation. Using these norms, we define hermitian vector bundles \( \mathcal{E}_D := (\mathcal{E}_D, (\| \cdot \|_{D, \sigma})_\sigma) \) over Spec \( R \).

We also choose an hermitian structure on \( \mathcal{P}^* \mathcal{L} \), and we denote \( \overline{\mathcal{P}}^* \mathcal{L} \) the so-defined hermitian line bundle over Spec \( R \). Finally, we equip \( T_P \hat{C} \) with an arbitrary
$R$-structure and with an hermitian structure, and in this way, we define another hermitian line bundle $\mathcal{T}_0$ over $\text{Spec } R$, such that $T_K = T_p \hat{\mathcal{C}}$.

We define the $K$-vector spaces $E_D := E_{D,K} = \Gamma(X, L^{\otimes D})$, their subspaces $E_D^i$, and the evaluation maps

$$\varphi_D^i : E_D^i \to (T^*_p \hat{\mathcal{C}})^{\otimes i} \otimes L^{\otimes D}_p.$$ 

as in the “local” situation considered in Section 4.B.

According to the basic algebraicity criteria in [13], 2.2, to prove that $\hat{\mathcal{C}}$ is algebraic, it suffices to prove that the ratio

$$\frac{\sum_{i \geq 0} (i/D) \text{rank}(E_D^i/E_D^{i+1})}{\sum_{i \geq 0} \text{rank}(E_D^i/E_D^{i+1})}$$

stays bounded when $D$ goes to $+\infty$.

For any place $v$ of $K$, the morphism $\varphi_D^i$ has a $v$-adic norm, defined by means of the integral and hermitian structures introduced above. If $\varphi_D^i \neq 0$, the height of $\varphi_D^i$ is the real number defined as the (finite) sum:

$$h(\varphi_D^i) = \sum_v \log \|\varphi_D^i\|_v.$$ 

When $\varphi_D^i$ vanishes, we define $h(\varphi_D^i) = -\infty$; observe that, in this case, $E_D^{i+1} = E_D^i$.

For any place $v$ of $K$, we let

$$\rho_v(L) = \limsup_{i/D \to \infty} \frac{1}{i} \log \|\varphi_D^i\|_v.$$ 

This is an element in $[-\infty, +\infty[$, and the discussion above concerning the definition of $\deg(T_p \hat{\mathcal{C}}, \|\cdot\|^{\text{can}})$ shows that

$$\rho_v(L) \leq -\log S_{\mathcal{X},v}(\hat{\mathcal{C}})$$

for any finite place $v$, and

$$\deg(T_p \hat{\mathcal{C}}, \|\cdot\|^{\text{can}}) = \sum_v (-\rho_v(L)) + \deg \mathcal{T}_0 = \sum_{v \text{ finite}} (-\rho_v(L) - \log S_{\mathcal{X},v}(\hat{\mathcal{C}})) + \sum_{v \text{ finite}} \log S_{\mathcal{X},v}(\hat{\mathcal{C}}) + \sum_{v \infty} (-\rho_v(L)) + \deg \mathcal{T}_0.$$ 

In this last expression, the terms of the first sum belong to $[0, +\infty]$ — and the sum itself is therefore well-defined in $[0, +\infty]$ — and the second sum is convergent by $A$-analyticity of $\hat{\mathcal{C}}$.

Actually, as established in the proof of Lemma 4.4 above (see also [12], Lemma 3.3), the following inequality holds for any finite place $v$, and any two positive integers $i$ and $D$:

$$\frac{1}{i} \log \|\varphi_D^i\|_v \leq -\log S_{\mathcal{X},v}(\hat{\mathcal{C}}).$$

Consequently the sum

$$\sum_{v \text{ finite}} \left( -\frac{1}{i} \log \|\varphi_D^i\|_v + \log S_{\mathcal{X},v}(\hat{\mathcal{C}}) \right)$$
Then, using (6.3), (6.4), and (6.5), we derive the upper bound

$$\limsup_{i/D \to \infty} \frac{1}{i} h(\varphi^i_D) \leq \sum_v \rho_v(L),$$

and

$$\limsup_{i/D \to \infty} \frac{1}{i} h(\varphi^i_D) - \deg(\nabla 0) \leq - \deg(T_p \hat{C}, \|\cdot\|^{\text{can}}).$$

\[(6.2)\]

Let $\mathcal{E}^i_D := \mathcal{E}_D \cap E^i_D$ and let $\mathcal{E}^i_D / \mathcal{E}^{i+1}_D$ be the hermitian vector bundle on Spec $R$ defined by the quotient $\mathcal{E}^i_D / \mathcal{E}^{i+1}_D$ equipped with the hermitian structure induced by the one of $\mathcal{E}_D$. The evaluation map $\varphi^i_D$ induces an injection $E^i_D / E^{i+1}_D \hookrightarrow (T_p \hat{C})^{\psi_i} \otimes I_{i/D}^D$. Actually, either $\varphi^i_D = 0$ and then $E^i_D = E^{i+1}_D$, or $\varphi^i_D \neq 0$, and this inclusion is an isomorphism of $K$-lines. In either case, we have:

$$\deg(\nabla 0) = \operatorname{rank}(E^i_D / E^{i+1}_D), \quad \left(\deg(\nabla \hat{\mathcal{L}} \otimes \hat{T}_0^y \otimes i) + h(\varphi^i_D)\right).$$

Indeed, if $\varphi^i_D = 0$, both sides vanish (we follow the usual convention $0.(\infty) = 0$). If $\varphi^i_D \neq 0$, the equality is a straightforward consequence of the definitions of the Arakelov degree of an hermitian line bundle over Spec $R$ and of the heights $h(\varphi^i_D)$.

The above equality may also be written:

$$\deg(\nabla 0) = \operatorname{rank}(E^i_D / E^{i+1}_D), \quad \left(\deg(\nabla \hat{\mathcal{L}} \otimes \hat{T}_0^y) + h(\varphi^i_D)\right).$$

Moreover, by [12], Prop. 4.4, there is a constant $c$, such that for any $D \geq 0$ and any saturated submodule $\mathcal{F}$ of $\mathcal{E}_D$

$$\deg(\nabla 0) \geq -cD. \operatorname{rank}(\mathcal{E}_D / \mathcal{F}).$$

(This is an easy consequence of the fact that the $R$-algebra $\bigoplus_{D \geq 0} \mathcal{E}_D$ is finitely generated.) Applied to $\mathcal{F} := \bigcap_{i \geq 0} \mathcal{E}^i_D$, this estimate becomes:

$$\sum_{i \geq 0} \deg(\nabla 0) \geq -cD. \sum_{i \geq 0} \operatorname{rank}(E^i_D / E^{i+1}_D).$$

When $\deg(T_p \hat{C}, \|\cdot\|^{\text{can}})$ is positive, the inequality (6.2) implies the existence of positive real numbers $\epsilon$ and $\lambda$ such that

$$\deg(\nabla 0) > \frac{\epsilon}{i} h(\varphi^i_D) \geq \epsilon \quad \text{for any two positive integers } i \text{ and } d \text{ such that } i \geq \lambda D.$$  

Then, using (6.3), (6.4), and (6.5), we derive the upper bound

$$\frac{\sum_{i \geq 0} (i/D) \operatorname{rank}(E^i_D / E^{i+1}_D)}{\sum_{i \geq 0} \operatorname{rank}(E^i_D / E^{i+1}_D)} \leq \lambda + \frac{c}{\epsilon}.$$

This completes the proof. $\square$
7. Rationality criteria

7.A. Numerical equivalence and numerical effectivity on arithmetic surfaces

The following results are variations on a classical theme of Arakelov geometry. The first theorem characterizes numerically trivial Arakelov divisors with real coefficients. It is used in the next proposition to describe effective Arakelov divisors whose sum is numerically effective. We allow ourselves to use freely the notations of [11].

**Theorem 7.1 (Compare [11], Thm. 5.5).** — Let $\mathcal{X}$ be a flat projective scheme over the ring of integers of a number field $K$ whose generic fibre is a smooth and geometrically connected curve. Let $(D, g)$ be any element in $\mathcal{D}_R^1(\mathcal{X})$ which is numerically trivial. Then there exist an integer $n$, real numbers $\lambda_i$ and rational functions $f_i \in K(\mathcal{X})^*$, for $1 \leq i \leq n$, and a family $(c_\sigma)_{\sigma: K \rightarrow \mathbb{C}}$ of real numbers such that $c_\sigma = c_\sigma$, $\sum c_\sigma = 0$, and $(D, g) = (0, (c_\sigma)) + \sum_{i=1}^n \lambda_i \text{div}(f_i)$.

*Proof.* — There are real numbers $\lambda_i$ and Arakelov divisors $(D_i, g_i) \in \mathcal{D}_R^1(\mathcal{X})$ such that $(D, g) = \sum \lambda_i (D_i, g_i)$. We may assume that the $\lambda_i$ are linearly independent over $\mathbb{Q}$. By assumption, the degree of $D$ on any vertical component of $\mathcal{X}$ is zero; the linear independence of the $\lambda_i$ implies that the same holds for any $D_i$. Let us then denote by $g_i'$ any Green current for $D_i$ such that $\omega(D_i, g_i') = 0$. One has

$$0 = \omega(D, g) = \sum \lambda_i \omega(D_i, g_i) = \sum \lambda_i \omega(D_i, g_i'),$$

so that the difference $g - \sum \lambda_i g_i'$ is harmonic, and therefore constant on any connected component of $\mathcal{X}(\mathbb{C})$. By adding a constant to some $g_i'$, we can assume that $g = \sum \lambda_i g_i'$. Then, $(D, g) = \sum \lambda_i (D_i, g_i')$. This shows that we may assume that one has $\omega(D_i, g_i) = 0$ for any $i$. By Faltings-Hriljac’s formula, the Néron-Tate quadratic form on $\text{Pic}^0(\mathcal{X}_K) \otimes \mathbb{R}$ takes the value $0$ on the class of the real divisor $\sum \lambda_i (D_i)_K$. Since this quadratic form is positive definite (see [46], 3.8, p. 42), this class is zero. Since the map from $\text{Pic}^0(\mathcal{X}_K) \otimes \mathbb{Q}$ to $\text{Pic}^0(\mathcal{X}_K) \otimes \mathbb{R}$ is injective, and since the $\lambda_i$ are linearly independent over $\mathbb{Q}$, the class of each divisor $(D_i)_K$ in $\text{Pic}^0(\mathcal{X}_K)$ is torsion. Since $D_i$ has degree zero on any vertical component of $\mathcal{X}$ and the Picard group of the ring of integers of $K$ is finite, the class in $\text{Pic}(\mathcal{X})$ of the divisor $D_i$ is torsion too. Let then choose positive integers $n_i$ and rational functions $f_i$ on $\mathcal{X}$ such that $\text{div}(f_i) = n_i D_i$. The Arakelov divisors $\text{div}(f_i) - n_i (D_i, g_i)$ are of the form $(0, c_i)$, where $c_i = (c_i, \sigma)_{\sigma: K \rightarrow \mathbb{C}}$ is a family of real numbers such that $c_i, \sigma = c_i, \sigma$ and $\sum c_i, \sigma = 0$. Then, letting $c_\sigma = \sum (\lambda_i / n_i) c_i, \sigma$, one has

$$(D, g) = (0, (c_\sigma)) + \sum \frac{\lambda_i}{n_i} \text{div}(f_i)$$

as requested. $\Box$

Let $M$ be a Riemann surface. Let $f_1, \ldots, f_n$ are meromorphic functions on a Riemann surface $M$, and $\lambda_1, \ldots, \lambda_n$ be real numbers, let $f \in C(M)^* \otimes_{\mathbb{Z}} \mathbb{R}$ be defined by $f = \sum_{i=1}^n \lambda_i \otimes f_i$. We shall denote by $|f|$ the real function on $M$ given by $|f| \lambda_i$, and by $\text{div} f$ the $\mathbb{R}$-divisor $\sum \lambda_i \text{div}(f_i)$; they don’t depend on the decomposition of $f$ as a sum of tensors. One has $\text{dd}^c \log |f|^{-2} + \delta_{\text{div}(f)} = 0$. 
We shall say that a pair \((D, g)\) formed of a divisor \(D\) on \(M\) and of a Green current \(g\) with \(L_1\) regularity for \(D\) is effective\(^{\text{(3)}}\) if the divisor \(D\) is effective, and if the Green current \(g\) of degree 0 for \(D\) is represented by a nonnegative summable function (see [11], Def. 6.1).

Similarly, we say that an Arakelov divisor \((D, g) \in \mathcal{Z}_R^1(\mathcal{X})\) on the arithmetic surface \(\mathcal{X}\) is effective if \(D\) is effective on \(\mathcal{X}\) and if \((D_C, g)\) is effective on \(\mathcal{X}(\mathbb{C})\).

We say that an Arakelov divisor, or the class \(\alpha\) of an Arakelov divisor, is numerically effective (in short, nef) if \([(D, g)] \cdot \alpha \geq 0\) for any effective Arakelov divisor \((D, g) \in \mathcal{Z}_R^1(\mathcal{X})\) (according to [11], Lemma 6.6, it is sufficient to consider Arakelov divisors with \(\mathcal{C}\) regularity). If \((D, g)\) is an effective and numerically effective Arakelov divisor, then the current \(\omega(g) := \text{dd}^c g + \delta D\) is a positive measure (see [11], proof of Prop. 6.9).

**Proposition 7.2.** — Let \(\mathcal{X}\) be a normal, flat projective scheme over the ring of integers of a number field \(K\) whose generic fibre is a smooth geometrically connected algebraic curve.

Let \((D, g)\) and \((E, h)\) be non-zero elements of \(\overline{\mathcal{Z}}_R^1(\mathcal{X})\); let \(\alpha\) and \(\beta\) denote their classes in \(\text{CH}_1^\text{R}(\mathcal{X})\). Let us assume that the following conditions are satisfied:

1. the Arakelov divisors \((D, g)\) and \((E, h)\) are effective;
2. the supports of \(D\) and \(E\) do not meet and \(\int_{\mathcal{X}(\mathbb{C})} g \ast h = 0\).

If the class \(\alpha + \beta\) is numerically effective, then there exist a positive real number \(\lambda\), an element \(f \in K(\mathcal{X})^\ast \otimes_{\mathbb{Z}} R\) and a family \((c_\sigma)_{\sigma: K \hookrightarrow \mathbb{C}}\) of real numbers which is invariant by conjugation and satisfies \(\sum_\sigma c_\sigma = 0\), such that for any embedding \(\sigma: K \hookrightarrow \mathbb{C}\),

\[ g_\sigma = (c_\sigma + \log |f|^2)^+ \quad \text{and} \quad h_\sigma = \lambda (c_\sigma + \log |f|^2)^-, \]

where \(\varphi^+ = \max(0, \varphi)\) and \(\varphi^- = \max(0, -\varphi)\), so that \(\varphi^+ - \varphi^- = \varphi\).

Moreover, \(\alpha^2 = \alpha \beta = \beta^2 = 0\).

**Proof.** — Since \((D, g)\) and \((E, h)\) are effective and non-zero, the classes \(\alpha\) and \(\beta\) are not equal to zero ([11], Prop. 6.10). Moreover, the assumptions of the proposition imply that

\[ \alpha \cdot \beta = \deg \pi_\ast (D, E) + \frac{1}{2} \int_{\mathcal{X}(\mathbb{C})} g \ast h = 0. \]

Since \(\alpha + \beta\) is numerically effective, it follows from Lemma 6.11 of [11] (which in turn is an application of the Hodge index theorem in Arakelov geometry) that there exists \(\lambda \in \mathbb{R}_+^\ast\) such that \(\beta = \lambda \alpha\) in \(\text{CH}_1^\text{R}(\mathcal{X})\). In particular, \(\alpha\) and \(\beta\) are nef, and \(\alpha^2 = \beta^2 = \alpha \cdot \beta = 0\).

Replacing \((E, h)\) by \((\lambda E, \lambda h)\), we may assume that \(\lambda = 1\). Then, \((D - E, g - h)\) belongs to the kernel of the canonical map \(\rho: \overline{\mathcal{Z}}_R^1(\mathcal{X}) \to \text{CH}_1^\text{R}(\mathcal{X})\), so is numerically trivial. By Theorem 7.1, there exist real numbers \(\lambda_i\), rational functions \(f_i \in K(\mathcal{X})^\ast\) and a family \(c = (c_\sigma)_{\sigma: K \hookrightarrow \mathbb{C}}\) of real numbers, invariant by conjugation, such that \(\sum_\sigma c_\sigma = 0\) and \((D - E, g - h) = (0, c) + \sum \lambda_i \text{div}(f_i)\) in \(\overline{\mathcal{Z}}_R^1(\mathcal{X})\). Let us set denote by \(f\) the element \(\sum f_i \otimes \lambda_i\) of \(K(\mathcal{X})^\ast \otimes_{\mathbb{Z}} R\). The proposition now follows by applying Lemma 7.3 below to the connected Riemann surface \(\mathcal{X}(\mathbb{C})\), the pairs \((D, g_\sigma), (E, h_\sigma)\) and the “meromorphic function” \(f \exp(-2c_\sigma)\), for each embedding \(\sigma: K \hookrightarrow \mathbb{C}\). 

\(^{\text{(3)}}\)In the terminology of [11], nonnegative
Let $M$ be a compact connected Riemann surface, let $D$ and $D'$ two nonzero $\mathbb{R}$-divisors on $M$, and let $g$ and $g'$ be two Green functions with $L^2$ regularity for $D$ and $D'$. We make the following assumptions: $|D| \cap |D'| = \varnothing$, the pairs $(D, g)$ and $(D', g')$ are effective, the currents $\omega(g) = dd^c g + \delta_D$ and $\omega(g') = dd^c g' + \delta_{D'}$ are positive measures, $\int_M g * g' = 0$. If there exists an element $f \in C(M)^* \otimes \mathbb{R}$ such that $g - g' = \log |f|^{-2}$, then $g = \max(0, \log |f|^{-2})$ and $g' = \max(0, \log |f|^{2})$.

**Proof.** — First observe that

$$\omega(g) - \omega(g') = dd^c (g - g') + \delta_D - \delta_{D'} = dd^c \log |f|^{-2} + \delta_D - \delta_{D'} - \text{div}(f),$$

by the Poincaré-Lelong formula. By assumption, the current $\omega(g) - \omega(g')$ belongs to the Sobolev space $L^2_{-1}$; it is therefore non-atomic (see [11], Appendix, A.3.1), so that $D - D' = \text{div}(f)$ and $\omega(g) = \omega(g')$.

Let $F$ be the set of points $x \in M$ where $|f(x)| = 1$ and let $\Omega = M \setminus F$ be its complementary subset. The functions $h = \max(0, \log |f|^{-2})$ and $h' = \max(0, \log |f|^{2})$ are (continuous) Green functions with $L^2_1$ regularity for $D$ and $D'$ respectively; the currents $dd^c h + \delta_D$, $dd^c h' + \delta_{D'}$ are equal to a common positive measure, which we denote by $\nu$. The classical formula $dd^c \max(0, \log |z|^2) = \frac{1}{2\pi} d\text{Arg} z \wedge \delta_{|z|=1}$ implies that one has $\nu = \frac{1}{2\pi} d\text{Arg} f \wedge \delta_{|f|=1}$. In particular the measure $\nu$ is positive and supported by $F$.

Let $S$ be the support of the positive measure $\omega(g)$. It follows from [11], Remark 6.5, that $g$ and $g'$ vanish $\omega(g)$-almost everywhere on $M$. Consequently, $\log |f|^{-2} = g - g' = 0$ $\omega(g)$-almost everywhere; in particular, $S \subset F$.

Let us pose $u = h - g = h' - g'$; this is a current with $L^2_1$ regularity on $M$ and $dd^c u = dd^c h - dd^c g = \nu - \omega(g)$. In particular, $dd^c (u|_\Omega) = 0$: $u$ is harmonic on $\Omega$. Since $g$ is nonnegative, one has $u \leq 0$ on $F = \Omega$. By the maximum principle, this implies that $u \leq 0$ on $\Omega$.

Finally, one has

$$0 = \int_M g * g' = \int_M h * h' - \int_M uv - \int_M u \omega(g) \geq \int_M h * h'.$$

By [11], Cor. 6.4, this last term is nonnegative, so that all terms of the formula vanish. In particular, $\int uv = 0$, hence $u = 0$ ($\nu$-a.e.). Using again that $u$ is harmonic on $\Omega$, it follows that $u \equiv 0$, q.e.d.

**Remark 7.4.** — The Green currents $g$ and $h$ appearing in the conclusion of the proposition are very particular. Assume for example that the Arakelov divisors $\hat{D}$ and $\hat{E}$ are defined using capacity theory at the place $\sigma$, with respect to an open subset $\Omega_\sigma$ of $X_\sigma$. Then, $g_\sigma$ and $h_\sigma$ vanish nearly everywhere on $\mathcal{C} \Omega_\sigma$. In other words, $\mathcal{C} \Omega_\sigma$ is contained in the set of $x \in X_\sigma$ such that $|f(x)|^2 = \exp(-c_\sigma)$, which is a real semi-analytic curve in $X_\sigma$, viewed as a real analytic surface. In particular, it contradicts any of the following hypothesis on $\Omega_\sigma$, respectively denoted (4.2)$_{X, \Omega_\sigma}$ and (4.3)$_{X, \Omega_\sigma}$ in [11]:

1. the interior of $\mathcal{X}_\sigma(C) \setminus \Omega_\sigma$ is not empty;
2. there exists an open subset $U$ of $\mathcal{X}_\sigma(C) \setminus |D|(C)$ not contained in $\Omega$ such that any harmonic function on $U$ which vanishes nearly everywhere on $U \setminus \Omega$ vanishes on $U$. 

7.B. Rationality criteria

Let $K$ be a number field, let $R$ be the ring of integers of $K$. Let $X$ be a smooth projective geometrically connected curve over $K$. For any place $v$ of $K$, we denote by $X_v$ the associated rigid analytic curve over $K_v$ if $v$ is ultrametric, resp. the corresponding Riemann surface if $v$ is induced by an embedding of $K \hookrightarrow \mathbb{C}$.

Moreover, for almost all ultrametric places $v$, $\Omega_v$ is the tube $|Z_v|$ around a closed Zariski subset $Z_v$ of its special fibre $X_{F_v}$, and $Z_v = D \cap X_{F_v}$ for almost all places $v$.

Our first statement in this section is the following arithmetic analogue of Prop. 2.2.

Proposition 7.5. — Let $X'$ be another geometrically connected curve over $K$ and $f : X' \to X$ be a non constant morphism. Let $D'$ be an effective divisor in $X'$. We make the following assumptions:

1. by restriction, $f$ defines an isomorphism from the subscheme $D'$ of $X'$ to the subscheme $D$ of $X$ and is étale in a neighbourhood of $|D'|$;
2. for any place $v$ of $K$, the morphism $f$ admits an analytic section $\varphi_v : \Omega_v \to X'_v$ defined over $\Omega_v$, whose formal germ is equal to $\hat{f}_{k_v}^{\sim}$;
3. the class of the Arakelov $\mathbb{Q}$-divisor $\hat{D}_\Omega$ is numerically effective.

Assume moreover

- either that $\hat{D}_{\Omega_1} \cdot \hat{D}_\Omega > 0$;
- or that there is an archimedean place $v$ such that the complementary subset to $\Omega_v$ in $X_v$ is not contained in a real semi-analytic curve of $X_v$.

Then $f$ is an isomorphism.

Proof. — Let us denote by $E$ the divisor $f^*D$ on $X'$; we will prove that $E = D'$.

Indeed, let $\mathcal{X}'$ denote the normalization of $\mathcal{X}$ in the function field of $X'$ and let us denote by $\hat{f}$ the natural map from $\mathcal{X}'$ to $\mathcal{X}$ which extends $f$. Then $\mathcal{X}'$ is a normal projective flat model of $X'$ over $R$. For any place $v$ of $K$, let $\Omega_v^1$, denote the preimage $f^{-1}(\Omega_v)$ of $\Omega_v$ by $f$. The complementary subset of $\Omega_v$ is a non-empty affinoid subspace of $X_v'_{\mathbb{C}}$ if $v$ is ultrametric, and a non-polar compact subset of $X_v'$ if $v$ is archimedean. Moreover, for almost all ultrametric places $v$, $\Omega_v$ is the tube around the specialization in $\mathcal{X}'_{\mathbb{C}}$ of $f^{-1}(D)$. In particular, the collection $\Omega_1 = (\Omega_v^1)$ is an adelic tube adapted to $|E|$.

We thus may assume that the capacitary metrics on $\sigma_{\mathcal{X}'}(D')$ and on $\sigma_{\mathcal{X}'}(E)$ relative to the open subsets $\Omega_v^1$ are induced by Arakelov $\mathbb{Q}$-divisors on $\mathcal{X}'$. Let us denote them by $\hat{D}_{\Omega_1'}$ and $\hat{E}_{\Omega_1'}$ respectively.

The notions of normality for schemes and analytic spaces coincide; since $X$ and $X'$ are normal, the image $\varphi_v(\Omega_v^1)$ of $\Omega_v^1$ by the analytic section $\varphi_v$ is a closed and open subset $\Omega_v^1$ of $\Omega_v$, containing $|D'|$, and the collection $\Omega^1 = (\Omega_v^1)$ is an adelic tube adapted to $|D'|$. Consequently, one has $\hat{D}_{\Omega_1'} = \hat{D}_1' \Omega_1'$. Similarly, denoting $\Omega^2_1 = \Omega_v \setminus \Omega^1_v$, the collection $\Omega^2 = (\Omega^2_v)$ is an adelic tube adapted to $|R|$ and $\hat{R}_{\Omega_1'} = \hat{R}_{\Omega_2'}$. One has $\hat{E}_{\Omega_1'} = \hat{E}_{\Omega_2'} = \hat{E}_1' \Omega_1'$. 

$f^*\hat D_Ω = \hat D_Ω^0 + \hat R_Ω^2$. Since $Ω_1^0 \cap Ω_2^0 = \emptyset$ for any place $v$, Lemma 7.6 below implies that $[\hat R_Ω^2] \cdot [\hat D_Ω^0] = 0$.

Since $\hat D$ is non-zero and its class is numerically effective, the class in $\widehat{\text{CH}}_0^1(\mathcal X')$ of the Arakelov divisor $f^*\hat D = \hat D + \hat R$ is numerically effective too. By remark 7.4, Prop. 7.2 applies under either of the hypotheses (4') or (4''). Necessarily $\hat R_Ω^2 = 0$. In particular, $R = 0$ and $E = D'$. It follows that $\text{deg}(f) = 1$ hence $f$ is an isomorphism.

**Lemma 7.6.** — Let $X$ be a projective smooth and geometrically connected curve over a number field $K$, let $D_1$ and $D_2$ be divisors on $X$ and let $Ω_1$ and $Ω_2$ be adelic tubes adapted to $|D_1|$ and $|D_2|$. Let us consider a normal projective and flat model $\mathcal X$ of $X$ over the ring of integers of $K$ as well as Arakelov divisors $\hat D_1Ω_1$ and $\hat D_2Ω_2$ inducing the capacitary metrics on $Ω_1(D_1)$ and $Ω_2(D_2)$ relative to the adelic tubes $Ω_1$ and $Ω_2$.

If $Ω_{1,v} \cap Ω_{2,v} = \emptyset$ for any place $v$ of $K$, then

$$\hat D_1Ω_1 \cdot \hat D_2Ω_2 = 0.$$

**Proof.** — Observe that $D_1$ and $D_2$ have no common component, since any point $P$ common to $D_1$ and $D_2$ would belong to $Ω_{1,v} \cap Ω_{2,v}$.

Let $\mathcal X$ be a projective flat model of $X$ where these classes live, namely $\hat D_iΩ_1 = (\mathcal D_i, g_i)$: $\mathcal D_i$ is the $\mathbb Q$-divisor on $\mathcal X$ extending $D_i$ defined by Prop. 5.1 and $g_i = (g_{D_i,Ω_1,v})$ is the family of capacitary Green currents at archimedean places. The vertical components of $\mathcal D_1$ and $\mathcal D_2$ lying over any finite place $v$ are distinct the one from the other, since $Ω_{1,v} \cap Ω_{2,v} = \emptyset$. Consequently, the geometric part of the Arakelov intersection product is zero. In view of [11], Lemma 5.1, the part at an archimedean place $v$ is zero too, since $Ω_{1,v}$ and $Ω_{2,v}$ are disjoint. This concludes the proof.

The following proposition makes more explicit the numerical effectivity hypothesis in Proposition 7.5.

**Proposition 7.7.** — Let $X$, $Ω$, $D$, $\mathcal X$, $\hat D_Ω$ be as in the beginning of this Subsection.

(a) If $D$ is effective, then $\hat D_Ω$ is an effective Arakelov divisor.

(b) Let us assume that $D$ is effective and write $D = \sum_i n_i P_i$ for closed points $P_i$ of $X$ and positive integers $n_i$. Then $\hat D_Ω$ is numerically effective if and only if $h_{DΩ}(P_i) \geq 0$ for each $i$.

(c) If $D$ is a rational point $P$, then $\hat D_Ω$ is numerically effective if and only if the Arakelov degree $\text{deg}(T_P X, \|\cdot\|_Ω^{\text{cap}})$ is positive.

**Proof.** — a) Let us assume that $D$ is an effective divisor. For each archimedean place $v$ of $K$, the capacitary Green function $g_{D,Ω_1}$ is therefore nonnegative ([11], 3.1.4). Moreover, we have proved in Prop. 5.1 that the $\mathbb Q$-divisor $\mathcal D$ in $Z_Ω^1(\mathcal X)$ is effective. These two facts together imply that $\hat D_Ω$ is an effective Arakelov divisor.

b) For any archimedean place $v$, the definition of the archimedean capacitary Green currents involved in $\hat D_Ω$ implies that $\omega(\hat D_Ω,v)$ is a positive measure on $X_v$, zero near $|D|$ ([11], Theorem 3.1, (iii)). By [11], Prop. 6.9, in order to $\hat D_Ω$ being numerically effective, it is necessary and sufficient that $h_{DΩ}(E) \geq 0$ for any irreducible component $E$ of $\mathcal D$. This holds by the construction if $E$ is a vertical component of $\mathcal X$: according to the
conditions of Prop. 5.1, on has $\mathcal{D} \cdot V = 0$ for any vertical components $V$ of the support of $\mathcal{D}$; for any other vertical component $V$, one has $\mathcal{D} \cdot V \geq 0$ because the divisor $\hat{D}_\Omega$ is effective. Consequently, $\hat{D}_\Omega$ is nef if and only if $h_{\hat{D}_\Omega}(P_i) \geq 0$ for all $i$.

c) By b), $\hat{D}_\Omega$ is numerically effective if and only if $h_{\hat{D}_\Omega}(P) \geq 0$. By the definitions of the height $h_{\hat{D}_\Omega}$ and of the capacitary norms on $T_P X$, this is in turn equivalent to the inequality $\deg(T_P X, \|\cdot\|_{\text{cap}}^\Omega) \geq 0$. 

\begin{corollary}
Assume moreover that $P$ is a rational point in $X(K)$. Let $\varphi \in \hat{\Theta}_{X,P}$ be any formal function around $P$ satisfying the following assumptions:

1. for any $v \in F$, $\varphi$ extends to an analytic meromorphic function on $\Omega_v$;
2. $\varphi$ is algebraic over $\Theta_{X,P}$;
3. $\deg(T_P X, \|\cdot\|_{\text{cap}}^\Omega) \geq 0$.

If equality holds in the preceding inequality, assume moreover that there is an archimedean place $v$ of $F$ such that $X_v \setminus \Omega_v$ is not contained in a real semi-analytic curve of $X_v$.

Then, $\varphi$ is the formal germ at $P$ to a rational function on $X$.

\begin{proof}
Let $X'$ be the normalization of $X$ in the field extension of $K(X)$ generated by $\varphi$; this is a smooth projective algebraic curve endowed with a finite morphism $f : X' \to X$ and the formal function $\varphi$ identifies with a formal section $\sigma$ of $f$ at $P$.

To show that $\varphi$ is the germ at $P$ of a rational function, it suffices to show that $f$ is an isomorphism. For any place $v$, $\Omega_v$ is a smooth analytic curve in $X_v$. Consequently, $\sigma$ extends to an analytic section $\sigma_v : \Omega_v \to X'_v$ of $f$. By Corollary 5.19, the Arakelov $\mathcal{Q}$-divisor $\hat{D}_\Omega$ attached to the point $P$ and the adelic tube $\Omega$ is nef. When $\deg(T_P X, \|\cdot\|_{\text{cap}}^\Omega)$ is positive, Prop. 7.5 implies that $f$ is an isomorphism, hence $\varphi$ is the formal germ to a rational function on $X$. This still holds when $\deg(T_P X, \|\cdot\|_{\text{cap}}^\Omega) = 0$, thanks to the supplementary assumption at archimedean places in that case.
\end{proof}

As an example, this theorem applies when $X$ is the projective line, $P$ is the origin and when, for each place $v$ in $F$, $\Omega_v$ is the disk of center 0 and of radius $R_v$ in the affine line, and if $\prod R_v \geq 1$. We then recover Harbater’s rationality criterion ([30], Prop. 2.1).

When $\deg(T_P X, \|\cdot\|_{\text{cap}}^\Omega) = 0$, some hypothesis on the sets $X_v \setminus \Omega_v$ is really necessary for a rationality criterion to hold. As an example, let us consider the Taylor series of the algebraic function $\varphi(x) = 1/\sqrt{1-4x} - 1$, viewed as a formal function around the origin of the projective line $\mathbb{P}^1_Q$. As shown by the explicit expansion

$$
\frac{1}{\sqrt{1-4x}} - 1 = \sum_{n=1}^{\infty} (-4)^n \frac{(-1/2)^n}{n!} x^n = \sum_{n=1}^{\infty} \frac{4^n}{n!} \frac{1 \cdot 3 \cdots (2n-1)}{2^n n!} x^n = \sum_{n=1}^{\infty} \binom{2n}{n} x^n,
$$

the coefficients of this series are rational integers. Moreover, the complementary subset $\Omega$ of the real interval $[1/4, \infty]$ in $\mathbb{P}^1(C)$ is a simply connected open Riemann surface on which the algebraic function has no ramification. Consequently, there is a meromorphic function $\varphi_\infty$ on $\Omega$ such that $\varphi_\infty(x) = (1 - 4x)^{-1/2} - 1$ around 0. One has $\text{cap}_0(\Omega) = 1$, hence $\deg(T_0 \mathbb{P}^1_\mathcal{Q}, \|\cdot\|_{\text{cap}}^\Omega) = 0$. However, $\varphi$ is obviously not a rational function.
By combining the algebraicity criterion of Theorem 6.1 and the previous corollary, we deduce the following result, a generalization to curves of any genus of Borel-Dwork's criterion.

**Theorem 7.9.** — Let $\varphi \in \widehat{\mathcal{O}}_{X,P}$ be any formal function around $P$ satisfying the following assumptions:

1. For any $v \in F$, $\varphi$ extends to an analytic meromorphic function on $\Omega_v$;
2. The formal graph of $\varphi$ in $\widehat{X} \times \mathbb{A}^1(\mathbb{P}(P))$ is $A$-analytic.

If moreover $\widehat{\deg}(T_P X, \| \cdot \|_{\text{cap}}) > 0$, then $\varphi$ is the formal germ at $P$ to a rational function on $X$.

**Proof.** — In view of Corollary 7.8, it suffices to prove prove that $\varphi$ is algebraic. Let $V = X \times \mathbb{P}^1$ and let $\widehat{C} \subset \widehat{V}(\mathbb{P}(P))$ be the formal graph of $\varphi$. We need to prove that $\widehat{C}$ is algebraic. Indeed, since at each place $v$ of $K$, the canonical $v$-adic semi-norms on $T_P \widehat{C}$ is smaller than the capacitary one, $\widehat{\deg}(T_P X, \| \cdot \|_{\text{cap}}) \geq \widehat{\deg}(T_P X, \| \cdot \|_{\text{can}}) > 0$. By Theorem 6.1, $\widehat{C}$ is then algebraic, and $\varphi$ is algebraic over $K(X)$. $\square$

Let us recall from Prop. 3.8 that the $A$-analyticity condition is automatically satisfied if there is a positive integer $N$ and a projective flat model $X'$ of $X$ over Spec $R[1/N]$ such that $\varphi$ extends to a regular formal function on the formal completion $\mathcal{X}_{J}$ at the Zariski closure $\mathcal{P}$ of $P$ in $X'$. Indeed, in that case, the formal graph of $\varphi$ extends to smooth formal curve over Spec $R[1/N]$.

Consequently, this theorem applies for example when, for each place $v$, $\Omega_v \subset F_v$ is the disk of center 0 and of radius $R_v$ in the affine line, and if $\prod R_v > 1$. We then recover Borel-Dwork's rationality criterion ([6, 21]). Similarly, the comparison of the capacitary norms with the transfinite diameter allow to recover the criterion of Pólya-Bertrandias ([39, 1]), at least when at finite places, the formal power series extends to an meromorphic function on open subsets $\Omega_v$ which are complements of affinoids. However, the strict inequality in the hypothesis of the theorem and the fact that compact subsets of $\mathcal{C}_p$ are contained in affinoids (actually, lemniscates) whose transfinite diameter is arbitrarily close allow easily to recover the full criterion from Theorem 7.9.

**Appendix**

**A. Metrics on line bundles**

Let $K$ be a field which is complete with respect to the topology defined by a discrete absolute value $| \cdot |$ on $K$. Let $R$ be its valuation ring and $\pi$ be an uniformizing element of $R$. We denote by $v = \log | \cdot | / \log |\pi|$ the corresponding normalized valuation on $K$.

Let $X$ be an algebraic variety over $K$ and let $L$ be a line bundle on $X$. In this appendix, we precise basic facts concerning the definition of a metric on the fibres of $L$.

Let $\overline{K}$ be an algebraic closure of $K$; endow it with the unique absolute value which extends the given one on $K$. It might not be complete, however its completion, denoted $C$, is a complete field containing $\overline{K}$ as a dense subset on which the absolute value extends uniquely, endowing it with the structure of a complete valued field.
A metric on the fibres of $L$ is the data, for any $x \in X(C)$, of a norm $\| \cdot \|$ on the one-dimensional $C$-vector space $L(x)$. Namely, $\| \cdot \|$ is a map $L(x) \to \mathbb{R}_+$ satisfying the following properties:

- $\|s_1 + s_2\| \leq \max(\|s_1\|, \|s_2\|)$ for all $s_1, s_2 \in L(x)$;
- $\|as\| = |a| \|s\|$ for all $a \in C$ and $s \in L(x)$;
- $\|s\| = 0$ implies $s = 0$.

We also assume that these norms are stable under the natural action of $\text{Gal}(C/K)$, namely that for any $x \in X(C)$, $s \in L(x)$ and $\sigma \in \text{Gal}(C/K)$, $\|\sigma(s)\| = \|s\|$.

We say a metric is continuous if for any open subset $U \subset X$ and any section $s \in \Gamma(U, L)$, the function $x \mapsto \|s(x)\|$ on $U(C)$ is continuous. This definition corresponds to that classical notion of a Weil function attached to a Cartier divisor on $X$ and will be sufficient for our purposes; a better one would be to impose that this function extends to a continuous function on the analytic space attached to $U$ by V. Berkovich [4]; see e.g. [29] for this point of view.

Assume that $X$ is projective and let $\mathcal{X}$ be any projective and flat $R$-scheme with generic fibre $X$, together with a line bundle $\mathcal{L}$ on $\mathcal{X}$ extending $L$. Let $x \in X(C)$; if $C^0$ denotes the valuation ring of $C$, there is a unique morphism $\varepsilon_x : \text{Spec } C^0 \to \mathcal{X}$, by which the generic point of $\text{Spec } C^0$ maps to $x$. Then, $\varepsilon_x^* \mathcal{L}$ is a sub-$C^0$-module of $L(x)$. For any section $s \in L(x)$, there exists $a \in C^0$ such that $as \in \varepsilon_x^* \mathcal{L}$. Define, for any $s \in L(x)$,

$$\|s\| = \sup\{|a| : as \in \varepsilon_x^* \mathcal{L}, \ a \in C \setminus \{0\} \}.$$  

This is a continuous metric on the fibres of $L$, which we call an algebraic metric.

Algebraic metrics are in fact the only metrics that we use in this article, where the language of metrics is just a convenient way of comparing various extensions of $X$ and $L$ over $R$. In that respect, we make the following two remarks:

1) Let $Y$ be another projective algebraic variety over $K$ and let $f : Y \to X$ be a morphism. Let $(L, \| \cdot \|_L)$ be a metrized line bundle on $X$. Then, the line bundle $f^* L$ on $Y$ admits a metric $\| \cdot \|_{f^* L}$, defined by the formula $\|f^* s(y)\|_{f^* L} = \|s(f(y))\|_L$, where $y \in Y(C)$ and $s$ is a section of $L$ in a neighbourhood of $f(y)$. Assume that the metric of $L$ is algebraic, defined by a model $(\mathcal{X}, \mathcal{L})$. Let $\mathcal{Y}$ be any projective flat model of $Y$ over $R$ such that $f$ extends to a morphism $\varphi : \mathcal{Y} \to \mathcal{X}$. Then, the metric $\| \cdot \|_{f^* L}$ is algebraic, defined by the pair $(\mathcal{Y}, \varphi^* \mathcal{L})$.

2) Let $\mathcal{X}$ be a projective and flat model of $X$ on $R$ and let $\mathcal{L}$ and $\mathcal{L}'$ be two line bundles on $\mathcal{X}$ which induce the same (algebraic) metric on $L$. If $\mathcal{X}$ is normal then the identity map $\mathcal{L}_K = \mathcal{L}'_K$ on the generic fibre extends uniquely to an isomorphism $\mathcal{L} \cong \mathcal{L}'$.

B. Background on rigid analytic geometry

The results of this appendix are basic facts of rigid analytic geometry: the first one is a version of the maximum principle, while the second proposition states that the complementary subsets to an affinoid subspace in a rigid analytic space has a canonical structure of a rigid space. They are well known to specialists but, having been unable to find a convenient reference, we decided to write them here.

Let $K$ be a field, endowed with a ultrametric absolute value, for which it is complete.

**Proposition B.1.** — Let $C$ be a smooth projective connected curve over $K$, let $f \in K(C)$ be a non constant rational function and let $X$ denote the Weierstrass domain $C(f) = \{x \in X : |f(x)| \leq 1\}$ in $X$. Then, any affinoid function $g$ on $X$ is bounded; moreover, there exists $x \in U$ such that

$$|g(x)| = \sup_{X} |g| \quad \text{and} \quad |f(x)| = 1.$$
The fact that \( g \) is bounded and attains it maximum is the classical maximum principle; we just want to assure that the maximum is attained on the “boundary” of \( U \).

**Proof.** — The analytic map \( f : \mathbb{C}^n \to (\mathbb{P}^1)^{\text{an}} \) induced by \( f \) is finite. It restricts to a finite map \( f_X : X \to B \), where \( B = \text{Spec} \mathcal{O}(X) \) is the unit ball. It corresponds to \( f_X \) a morphism of affinoid algebras \( K(t) \to \mathcal{O}(X) \) of algebras which makes \( \mathcal{O}(X) \) a \( K(t) \)-module of finite type. Let \( g \in \mathcal{O}(X) \) be an analytic function. Then \( g \) is integral over \( K(t) \), hence there is a positive integer \( n \), as well as analytic functions \( a_i \in K(t) \), for \( 1 \leq i \leq n \), such that

\[
g(x)^n + a_1(f(x))g(x)^{n-1} + \cdots + a_n(f(x)) = 0
\]

for any \( x \in X \). It is classical (see [25], p. 70–71) that for any \( t \in B \),

\[
\sup_{f(x) = t} |g(x)| = \max_{1 \leq i \leq n} |a_i(t)|^{1/i}.
\]

The proof of the maximum principle on \( B \) shows that for each integer \( i \in \{1, \ldots, n\} \) a point \( t_i \in B \) satisfying \( |t_i| = 1 \) and \( |a_i(t_i)| = \|a_i\| \). There is therefore a point \( t \in B \) such that \( |t| = 1 \) and

\[
\max_i |a_i(t)|^{1/i} = \max_i \|a_i\|^{1/i}.
\]

Any point \( x \in X \) such that \( f(x) = t \) satisfies \( |f(x)| = 1 \) and \( |g(x)| = \|g\| \).

**Proposition B.2.** — Let \( X \) be a rigid analytic variety over \( K \) and let \( A \subset X \) be the union of finitely many affinoid subsets.

Then \( X \setminus A \), endowed with the induced \( G \)-topology, is a rigid analytic variety.

**Proof.** — By [7], p. 357, Prop. 9.3.1/5, and the remark which follows that proposition, it suffices to prove that \( X \setminus A \) is an admissible open subset.

Let \( (X_i) \) be an admissible affinoid covering of \( X \); then, for each \( i, A_i = A \cap X_i \) is a finite union of affinoid subsets of \( X_i \). Assume that the Proposition holds when \( X \) is affinoid; then, each \( X_i \setminus A_i \) is an admissible open subset of \( X_i \), hence of \( X \). Then \( X \setminus A = \bigcup_i (X_i \setminus A_i) \) is an admissible open subset of \( X \), by the property (G\(_i\)) satisfied by the \( G \)-topology of rigid analytic varieties.

We thus may assume that \( X \) is an affinoid variety. By Gerritzen-Grauert’s theorem ([7], p. 309, Cor. 7.3.5/3), \( A \) is a finite union of rational subdomains \( (A_i)_{1 \leq i \leq m} \) in \( X \). For each \( i \), let us consider affinoid functions \( (f_{i,1}, \ldots, f_{i,n_i}, g_i) \) on \( X \) generating the unit ideal such that

\[
A_i = X \left\{ f_{i,1}, \ldots, f_{i,n_i}, g_i \right\} = \{ x \in X ; |f_{i,1}(x)| \leq |g_i(x)|, \ldots, |f_{i,n_i}(x)| \leq |g_i(x)| \}.
\]

We have

\[
X \setminus A = \bigcap_{i=1}^m (X \setminus A_i) = \bigcap_{i=1}^m \bigcup_{j=1}^{n_i} \{ x \in X ; |f_{i,j}(x)| > |g_i(x)| \}.
\]

Since any finite intersection of admissible open subsets is itself admissible open, it suffices to treat the case where \( m = 1 \), i.e., when \( A \) is a rational subdomain \( X(f_{1, \ldots, f_{n}, g}) \) of \( X \), which we now assume.

By assumption, \( f_{1, \ldots, f_{n}, g} \) have no common zero. By the maximum principle ([7], p. 307, Lemma 7.3.4/7), there is \( \delta \in \sqrt{|K^\times|} \) such that \( \max(|f_{1}(x)|, \ldots, |f_{n}(x)|, |g(x)|) \geq \delta \) for any \( x \in X \). For any \( \alpha \in \sqrt{|K^\times|} \) with \( \alpha > 1 \), and any \( j \in \{1, \ldots, n\} \), define

\[
X_{j, \alpha} = X \left\{ \delta \frac{1}{f_j}, \alpha^{-1} \frac{g}{f_j} \right\} = \{ x \in X ; |f_j(x)| \alpha |g(x)| \leq |f_j(x)| \}.
\]
This is a rational domain in $X$. For any $x \in X_{j,a}$, one has $f_j(x) \neq 0$, and $|g(x)| < |f_j(x)|$, hence $x \in X \setminus A$. Conversely, if $x \in X \setminus A$, there exists $j \in \{1, \ldots, n\}$ such that $\max(|f_1(x)|, \ldots, |f_n(x)|, |g(x)|) = |f_j(x)| > |g(x)|$; it follows that there is $\alpha \in \sqrt{\mathbb{K}^*}$, $\alpha > 1$, such that $x \in X_{j,a}$. This shows that the affinoid domains $X_{j,a}$ of $X$, for $1 \leq j \leq n$ and $\alpha \in \sqrt{\mathbb{K}^*}$, $\alpha > 1$, form a covering of $X \setminus A$.

Let us show that this covering is admissible. Let $Y$ be an affinoid space and let $\varphi : Y \to X$ be an affinoid map such that $\varphi(Y) \subset X \setminus A$. By [7], p. 342, Prop. 9.1.4/2, we need to show that the covering $(\varphi^{-1}(X_{j,a}))_{j,a}$ of $Y$ has a (finite) affinoid covering which refines it. For that, it is sufficient to prove that there are real numbers $\alpha_1, \ldots, \alpha_n$ in $\sqrt{\mathbb{K}^*}$ and greater than 1 such that $\varphi(Y) \subset \bigcup_{j=1}^n X_{j,a}$.

For $j \in \{1, \ldots, n\}$, define the affinoid subspace $Y_j$ of $Y$ by

$$Y_j = \{ y \in Y : |f_j(\varphi(y))| < |f_j(\varphi(y))| \text{ for } 1 \leq i \leq n \}.$$ 

Since $\varphi(Y) \subset X \setminus A$, one has $Y = \bigcup_{j=1}^n Y_j$. Moreover, for each $j \in \{1, \ldots, n\}$, $f_j \circ \varphi$ does not vanish on $Y_j$, hence $g \circ \varphi / f_j \circ \varphi$ is an affinoid function on $Y_j$ such that

$$\left| \frac{g \circ \varphi}{f_j \circ \varphi}(y) \right| < 1$$ 

for any $y \in Y_j$. By the maximum principle, there is $\alpha_j \in \sqrt{\mathbb{K}^*}$ such that $\alpha_j > 1$ and $\left| \frac{g \circ \varphi}{f_j \circ \varphi} \right| < \frac{1}{\alpha_j}$ on $Y_j$. One then has $\varphi(Y) \subset \bigcup_{j=1}^n X_{j,a}$, which concludes the proof of the proposition.
